3. 10 Meter SSB freqs

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-01 17:30:34 UTC
From: Bob Liesenfeld <robert.liesenfeld@neicoltech.org>
Message-ID: <3F01C53A.448D18F3@neicoltech.org>

Hi gang,
Ok, with the declining nature of the current solar cycle, I figure I just about have time to build a dream project before the next peak hits. ;)

My plan is for the following:
Handheld xcvr (not cell phone tiny, more like the size of a larger brick).
Long loaded telescoping whip antenna
SSB
2-4 W output.

I plan to use either a synthesizer I have been playing with, or some incantation of the "Huff & Puff" stabilizer. However, I need to pick a range of frequencies for it as that will have a dramatic impact on the synth/H & P circuitry.
Since I have never spent much time on 10, I wondering what the common wisdom is for where the SSB activity is on this band. I would like to keep the tuning range down to 100KHz if possible, but especially with the H & P idea, I could go to say, 500KHz.

Any thoughts?

Bob 'POQ

I'll bet they are NOT car batteries either. They are (or certainly should be) some sort of Sealed Lead Acid (SLA) like glassmat unless they came from some UPS service in a specially designed ventilated area. Car batteries are NOT sealed and they DO emit explosive hydrogen gas when charging and should only be used in a well ventilated area (not under the radio desk in your house).

9. DDS/PLL Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-02 00:03:37 UTC
From: JLB <IHateSpam@nospam.net>
Message-ID: <ubpMa.753$_83.476@fe01.atl2.webusenet.com>
Source record: 34576

Typically the DDS is used as the reference oscillator for the PLL, resulting in the VCO being at a multiple of the DDS output frequency. The idea being that the VCO output will have decent phase noise performance with the fine frequency resolution of the DDS, and resaonably fast stepping times---"the best of both worlds", you might say.

I discovered an interesting alternative at :
http://lea.hamradio.si/~s57nan/ham_radio/dds_9851/dds_9851.html

This idea has the DDS acting as a programmable divider inside the PLL feedback loop. Ok, what are the advantages or disadvantages of doing this? What does it do to the phase noise and lock-up time? And what about the spurs?

If you have to stick with a 100KHz swath, 28400-28500 is the segment to use - and you'll find plenty of activity there. If you can expand the coverage it's worthwhile to cover 28300-28700. (actually if it were my project I'd do 28000-28500 and provide for CW<grin>)

Any recommendations on the best products to achieve as complete a range of reception and transmission as possible? All band, all mode, CW, VLF, Low Band, VHF, UHF, AM aircraft, etc.? Kenwood TS-2000? Harris? Is there an all-in-one radio? I've got six old radios (tube sets mostly) to accomplish this, and would like to get more space and tech efficient. I just don't know the new products. Suggestions?

Spurious are down to normal analogue pll levels.

As is phase noise.

Lock-up time is somewhat slower than the DDS, this is reduced down to normal PLL
times as well.

Doing it this way gives you one advantage over a normal analogue pll - small
frequency steps (= normal analogue pll with fractional divider).

International Rectifier has an entire section on their website for the testing methodology for MOSFET's --
their were also several FET tester circuits in "Ham Radio" magazine -- one of the great bargains is to have the collection on CD-ROM. Do you have a FAX --email me privately and I'll send a copy.

I've got CAT5 Etherenet in my house (even in my shack) and have no problems either way. CAT5 is balanced and very tightly twisted so there is not a lot of leakage. You wouldn't want to run an antenna right next to it, but it is fine for a normal installation.

Doug -

"Properly installed" should be NO problem

I installed miles of Cat 5 running Ethernet at a major hospital.

Due to ICU, Surgery, Radiology and Lab departments, we swept the entire area
for
any potential interference - which would interfere with patient support
equipment.

NONE. The industry does not need "urban legends"

"Properly installed" is the key aspect --- and their are a number of
certification organizations
for installers and contractors.

I am hoping that someone could help in finding voice activation switch IC.

I did find one or two very old references to a Motorola MC2830P, but have a feeling that it is discontinued as I was unable to find any information on the Motorola site.

I have found a few circuits on the web, but was hoping someone here might have used something that they would recommend. Something with a low parts count, and might work with an inexpensive computer microphone or a headset microphone meant for hands free telephone conversations.

It only needs to be momentary on. Some sort of gain adjustment or background filtering would be valuable.

any leads?

thanks
andy

In my experience at home and at work, it's OK unless and untill a
hub, switch, or NIC decides to get noisy. Then it's time to get out
the handheld scanner and start tracking it down. The radio shop at
WeBuildHighways, my day job, had a bad switch, and it took a day to
find out what was trashing their VHF reception.

Aside from that, it's just fine.

These days it is not so much of a problem to construct a receiver that
can be tuned to any frequency between 9 kHz and 9 GHz, the problem is
building a receiver that is actually usable in that frequency
range:-).

If such large frequency range would be attempted, the local oscillator
phase noise would kill the performance completely. Wide open receiver
front ends will also very easily overload, producing a huge number of
spurious responses.

Doing a high quality DC to daylight receiver would require at least 3
or 4 different receiver topologies. One perhaps from 9 kHz to 1500
kHz, one from 1 MHz to 200 MHz, one from 100 MHz to 10 GHz and one for
frequencies above 10 GHz (if needed).

Each subreceiver would require at least a dozen of fixed input filters
or at least 4-5 tunable front end filters each, since it is hard to
make a tunable filter with a frequency range larger than 1:3. Even
with strong mixers a selective front end filter will help in keeping
the spurious responses at a reasonable level.

I would strongly recommend that you keep your old tube equipment,
since they will very clearly outperform any "DC to daylight" all in
one units at least in LF and MF.

In HF, a DC to daylight receiver will outperform the tube set in
frequency display accuracy and frequency stability, but _definitively_
not in spurious response. At frequencies above 15-30 MHz a new rig may
outperform a tube rig in sensitivity.

Above 50-100 MHz even a mediocre modern receiver may outperform an old
tube receiver.

Well, I guess the death knell has sounded for the Shack as a source for experimenter and hobbyist parts. I went into a relatively new store (open less than a year) today to get a few resistors that I need in a hurry. What did I find? Not a resistor, capacitor, transistor, IC, switch, fuse, or anything that would be considered an electronic component was to be found. They had all kinds of TV coax, TV connectors, cell phones, home phones, phone accessories, satellite TV equipment, expensive toys, and a few stereo "systems", but but not an electronic component in sight. They had wire, solder, soldering irons, and such, but nothing to solder the wires to. They don't even carry the small project boxes any more.
They're looking more like the electronics section in WalMart every day.
Ooops, I take that back... the Shack's prices are 40-100% above what you'll pay for the same item at WalMart.

Adios Radio Shack !! RIP

Just think about where you are going to get the base drive if the pass transistor is in the positive lead. You'll need a voltage considerably higher than the output voltage. This may demand that the rectifier put out more voltage than you'd really like, which means more drop across the pass transistor and thus more dissipation (lower efficiency).

It's easy to get the supply for the base of the pass transistor if it is in the return lead, without increasing the rectifier output voltage above the minimum required to always overcome the drop in the pass transistor.

32. Power supply topology question

Not infrequently regulated power supply circuitry is found with NPN pass transistors like the 2n3055, in the negative supply line,

I'm curious to know what are the pros and cons of putting the pass transistors in this way, as against the more common topology of putting them in the positive supply line?

Thanks

MikeN

my local RS had a pretty good selection of basic parts (2n2222's
resistors, tools, caps, etc) until last fall when they just decided, for
no apparent reason, to stop carrying them. They lost my business. Now I
drive into Montreal to goto ABRA, much cheaper parts ($0.05 each for
capacitors), but the cost of gas makes it impractical to go for less
than $20 of parts.

It's a sad thing.

My local Radio Shack is run by a fellow that stocks parts. Not the RS brand, but Ohmite and others. We have a college in that town and an electrical engineering department, so I guess that one doesn't count. A company store, 45 miles away, has an upright cabinet with drawer with resistors, ICs, Caps and other parts. Not a good selection, but some. Another store 35 miles away has the same kinda drawers with the same kinda items.

The seem to want to sell (and promise the moon) on appliance items.

And we only have ourselves to blame. How many of us, Licensed Amateurs, not members of this group, but individuals who hold a license, know one end of a soldering iron form another. Radio Shack is a BigBoard listed corporation. The Board of Directors has a responsibility to increase shareholder wealth. Those of us that do build something, have other places to buy where we can get it cheaper, and we do most of our shopping at that source. Then comes the need for a 48.5 ohm 2.5 watt resistor NOW. We race to Rat Shack, and then when such a "common" item is not available bad mouth them. If they sold more components they would carry more components. They carry a bunch of them now, there just not hung on the wall anymore. The parts are in 8 drawer cabinets, depending on what the store sold in parts prior to the conversion, about ten months ago the stores have 4 or 8 of these cabinets. There is a lot of stuff not in the store that they can get for you. All you have to do is ask. The quote 10 working day delivery (better to over deliver than over promise). In my experience delivery time for the non-stock item is two to three days. I don't work there anymore, but I still shop there, and will continue to.

One possible benefit is transistor is connected collector grounded.
There is no need
insulate the transistor and heat conduction is improved.

Possible problems may be in cases where for some reason the regulation
transistor fails,
unregulated and higher overvoltage can get to load if there is any
return path from ground to
unregulated negative line. Possibly transistor in negative line has
infinite
resistance when failed.

Some sort of overvoltage protection could be useful if the load is
sensitive to overvoltages.

We used to have "Tandy" stores over here in the UK,
which were always poor substitutes to your Radio Shack
shops, but which nevertheless sold a decent proportion
of components and other stuff for constructors.
Suddenly, for whatever reason, they sold all the stuff off cheap and started
selling accessories for mobile phones and domestic TV and Hi Fi bits and
pieces.
Even Maplin Electronics over here is cutting stocks back - when you order
now you are told quite often they haven't the quantity you require and it
has to go on back
order!
Anyone would think that home construction was a dying hobby!

Duncan Walters wrote:

>Anyone would think that home construction was a dying hobby!

Supplies of components for home construction are actually better than they have ever been. The difference is how we get hold of them.

As everybody points out, when you need a 22K resistor it's no longer possible to go to a local store. Too bad - so get over it and move on.

Instead you have to stock ordinary small components *yourself*, and plan ahead for larger projects.

One of the best investments I ever made for home construction was a set of plastic drawers and a kit of 0.25/0.5W resistors in standard values from 10 ohms up to 1M. Also I keep a reasonable supply of small capacitors, for example 0.001, 0.01 and 0.1uF for RF bypassing, and an assortment of low-value ceramic plate caps. There are plenty more drawers left for other components I know I'm going to need regularly.

It's not overly expensive to build up a basic stock like this - and you'll never be caught wanting a 22K resistor again!

Where do you buy these components? By mail order from the big distributors like Farnell and Rapid Electronics in the UK, and Digi-Key and Mouser in the USA. These are also the places we now have to go with the shopping-list for larger projects. They have a huge range of components and they will deal with amateurs if we're businesslike about it. It's mostly a matter of planning what we need.

Part of this planning is to keep a list of items that are running low and will soon need to be topped-up. That way, lots of small things will add up to make your next large order. It's also a more cost-effective way to deal with minimum order and shipping charges.

My August 'In Practice' column in RadCom will be about buying from the professional distributors (in the UK). I repeat this same basic information every year or two in the magazine, but also maintain a permanent web page on UK component and tool suppliers, and how to order from them:
www.ifwtech.co.uk/g3sek/in-prac/components.htm

As I say, in reality the situation has never been better! It's we ourselves who need to change our buying habits.

Better yet of course, is SMT Ian. If you can use half an order of FST-3125's, (1250), I can buy them at $0.22 each.

At $0.86 each in single quantity, they're still cheaper than an MCL mixer/switch, by 5X at least. And, yield greatly improved performance to boot!

Not that I think RS is wonderful, but the present-day choice seems to be Radio Shack or nothing for "right now" purchases.

Unless you have a real electronic wholesaler in town that will deal with small orders, or are willing to wait a few days for DigiKey, Mouser, etc.

And it's easy to see why they would rather sell $99.95 JunkSonic items rather than $1.49 capacitors.

My local Radio Shack INCREASED the amount of parts they carried a couple of months ago. They moved all the parts from the wall racks to a couple of cabinets, but in the process, increased the number of different types they stocked.

I'm not sure what you mean by "a full oscillator." You could use a simple buzzer or a Mallory Sonalert. The latter has a pleasant tone. I made a mechanical oscillator out of a small speaker once by substituting a couple of silver plated wires cut from old diodes for one of the flexible wires connecting to the voice coil. You adjust the wires so they just make contact normally, then wire the thing to a flashlight cell and a key, setting the polarity so that the cone moves to open the contact. Kinda raucus(sp) but it worked.

Thanks for the input. I did searches all over the place but missed the one by "guessing" It looks like the one I found here: http://ourworld.compuserve.com/homepages/Bill_Bowden/page10.htm#tone.gif

I will put this together this weekend and see how it goes.

Well, they still have fuses and light bulbs, at least.

Digi-Key has, in the past decade or so, gotten really good at carrying RF inductors and capacitors. They even have a small assortment of microwave parts now. I think that homebrewing could be entering a renaissance age of using all the really good radio stuff that is permeating everywhere.

Recently I built a 1.6 GHz LNA with a 0.5 dB noise figure... using about $5 in parts from Digi-Key. This *is* the dawn of a new age in homebrewing.

Tim.

Agreed.

I contend that the NUMBER of people homebrewing is probably about the same
as ages ago, it's just a much smaller percentage of the ham population. And
the field is so much wider that it's hard to stock everything everyone
wants.

Back when 100 tube types would satisfy most demands, 10 or 20 variable
capacitors, 10% 1/2-W and 1-W Allen-Bradley resistors were enough, etc, etc,
the stocking challenge wasn't so big.

The amount of RF required to interfere with a sensitive RF
receiver is quite a few magnitudes less than what would
interfere with patient support equipment.

And this has been seen as the cause of the disappearance of the local
electronic outlet. Even in 1971 when I first entered one of those stores,
there was an awful lot of overlap between the needs of the electronic repair
person and the electronic hobbyist. Most of the parts I bought had
uses elsewhere, and the relatively few parts that weren't, like variable
capacitors, weren't much of a burden.

Even a few years later, I had to go to a different breed of stores to
buy ICs, because the old stores weren't carrying much in that area
(other than costly replacement line devices). The old stores started
fading out, unable or unwilling to make the transition. Face it,
those old stores had been around for a long time, with those wooden
floors and plenty of WWII surplus, and if for no other reason, it
was probably seen by many as a good time to retire or move on, rather

than expend money on new stock and even new decor.

The problem with the newer distributors were that they often didn't carry radio parts, and sure didn't carry surplus. Likely because the component count went way up, and they had to stop somewhere. Instead of one-stop locations, you'd have to go to a few places, and maybe mail order for some. Many of the newer stores seemed more interested in only professional sales, so they didn't want those hobbyists hanging around on Saturday mornings which is what happened at the old stores (and created the atmosphere). Actually, the newer distributors weren't the type of place you wanted to hang out. I remember going to Active circa 1975 or 76, and you entered a tiny reception room where you filled out an order form, and someone in the back collected the parts.

Radio Shack was handy for some parts, but I never routinely bought there because the prices were too high, and I couldn't get everything there. On the other hand, I never had the animosity that some seem to have for the place, ironically from those who never seemed to buy parts elsewhere. But the parts there likely were balanced against the equipment the stores were selling, and they were seen in seen way as beneficial. For whatever reason(s), in recent years that benefit seems to have diminished, so the parts are disappearing from Radio Shack.

This is 25 to 30 years after those parts stores I first went to at age 11 started disappearing.

Ramsey electronics has a voice operated switch kit:
http://www.ramseyelectronics.com/

It is not a low parts count, but it's relatively cheap and might
be an option for you.

I will admit to being spoiled.

Those in the Boston area are familiar with You-Do-It Electronics here
in Needham (aka You-Blew-It). I have managed to stump them a few
times, but I had to really work at it.

There are others in the area, no particular reason for me to seek them
out.

A history of high-tech manufacturing in the area probably enhances the
odds of something similar.

Ours generates noise on HF. I have a vertical antenna about 15 feet
from the house and that doesn't help. We didn't have problems with
the old-style coax cable ethernet. I'll switch to shielded cat-5
cable in the near future.

Maplin (England) has some 1000 pF and 0.1 uF feedthrus at a very attractive
price. May be surplus, they don't look new, but conversely, I don't think
they've been used before either.

Franchise stores have a great degree of flexibility; the Shack in Lincoln
City, OR, not only stocks componets well, but also has S&W revolvers.

http://www.bizcenter.org/ClientStories/radioshack.pdf
http://www.valuecom.com/acclaim/Oregon/Computers_and_Internet/The_Electronic_Superstore.ht
ml

Company stores, on the other hand, are often hopeless.

So sayeth a former two-store Shack manager.

They are physically different.

They are basically a way of getting something in or out of a chassis
or compartment without any associated RF.

So all feedthrough capacitors fit in some kind of hole. Some have a thread
so you can hold it in place with a nut. Others are soldered in place. The
center lead obviously carries the signal you want, but from that point to
ground there is a (pretty good) capacitor to ground. No extra leads to
cause problems, likely because of the physical layout less chance for
a stray signal to come out of (or into) the box.

At the very least, they are a neat way of hooking wires to a box,
since they in effect supply terminals that you can solder wires to.

Joe -

Let's look at the obvious.

The MC designation is Motorola Semiconductor. The Motorola division that produced analog, logic and discrete semiconductors was "spun off" into ON Semiconductor www.onsemi.com/

There are companies that have a wide assortment of new and obsolete Motorola semiconductors

A quick search of http://www.1sourcecomponents.com/

Shows this part IN STOCK

Maybe you saw my comment in rec.radio.shortwave earlier today.

As I said over there, just last week I decided to check the site,
since sometimes he has things on sale, and got a "404 error"
for the old URL, http://www.fix.net/dans.html A websearch found this new
URL.

It was a surprise to find that the old URL was not working, and
my first thought was the worst. It had been a few weeks, at least,
since I last checked the site. I don't recall seeing any mention of
the new URL, but perhaps it was aliased to the old site for a while,
and the only one just expired recently.

70. Homebrew in north Seattle/Everett area? Or a FAQ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-04 01:37:27 UTC
From: Harry George <hgg9140@seanet.com>
Message-ID: <m3ptkrul60.fsf@wilma.local>
Source record: 34488

I've just gotten into Amateur Radio, and am setting up a workshop for homebrew. I understand my local radio club isn't much on homebrew. Anyone in this area available to give me some pointers? Or maybe there is a FAQ for this newsgroup?

I've already gotten some designs from ARRL sites and books, plus some general web searching. I have Digikey, Allied, and Radio Shack catalogs, but need "used parts" sources.

71. NE570N

Cleaning out my garage, I found a NE570N IC that I bought for a project a few years ago. I never built the project and no longer have the plans. Looking through Google, I see the NE570N is now obsolete. If anyone has a need for this IC drop me a line. Best of all, it's free.

The easiest circuit uses an XR2206 IC. They are a couple of bucks and will
give a pure sinewave.
Sure sounds a lot better than a 555 timer

Jim -

Shielded twisted pair is included within the EIA/TIA 568 standard
and is used in parts of Europe. It is more expensive to install and takes
more time to terminate (but less than the old IBM Type 1 cabling system !!)

I will only speak for what I know, have observed in the field or tested in
the biomed labs.

When testing commenced in 1992 at Mercy, we found the majority of the
problems were with
switching power supplies that powered the network and computer equipment.
Our discoveries and test results forced Compaq to recall equipment for noise
and
improper grounding [One bad Chinese supplier - they were using several at
that time].

Coax [10-Base-T] will limit you to standard Ethernet speed (10 Mb) - and is
subject to the
quality of cable and its coax shielding - which is why Belden has specific
model number of Thick and Thin
Ethernet.

Fiber Optic is ideal - but you have termination costs and again power issues
with equipment.

I have not yet tested any of the upcoming 802.3af equipment ("power for phones") -
yet another potential to examine in the "wiring closet".

Whoops. I wrote most of my reply, below, before noticing that the FAQs
do in fact have this information in them. These links ought to get
you started:

http://www.repairfaq.org/ELE/F_surplus_us6.html#SURPLUSUS_012
http://www.qsl.net/pnwvhfs/resources/vendors.htm

Since I've already written my own version of this information, I'll
include it:

>I've already gotten some designs from ARRL sites and books, plus some
>general web searching. I have Digikey, Allied, and Radio Shack
>catalogs, but need "used parts" sources.

Let's see. You'll probably want to know about Vetco, in Bellevue; they
sell surplus parts of all kinds. Their stock got a bit smaller and less
eclectic when they moved into their current space, a few years ago, but
they're still worth visiting.

There used to be a Radar Electronics in dowtown Seattle, on Western,
which had quite a good selection of "electronics for industry"
(think a retail version of Mouser/DigiKey) as well as surplus
in the back. I gather they've moved up north and dropped the surplus
section, but they're probably still a good source for when you want
something today and are willing to pay the retail price.

I'm told that the surplus guy from Radar opened his own store, which
some googling reveals to be "House of Science"[1]. Also in that general
area is "The Old Technology Shop", which tends more towards vintage
audio gear, but can be good also[2].

A place not mentioned in the FAQ links above is the University of
Washington Surplus Property Auction[3]. Extremely variable, even moreso
than Boeing Surplus, but occasionally some good stuff.

[1] http://houseofscience.com/ (horrible page design, though)
[2] 7712 Aurora Ave North; I can't find a website for them
[3] http://www.washington.edu/admin/surplus/

I did see the kit, but wanted to see if I could make something myself first.

There was a suggestion to us a microcontroller, and I am now considering the use of the analogue comparator on an AVR microcontroller that will be being used in the project.

It seems that most VOX circuits boil down to comparing a microphone voltage to a threshold reference. I am not really to experienced in audio filtering and amplification, so I would have to find some web documentation on making a circuit to handle the sound in portion. I suppose it would even be possible to have one of the PWM channels on the microcontorller set the reference voltage, and in this way it would be adjustable.

If anyone has some tutorial sights on sound handling hardware (filter, amplify, etc) please suggest.

cheers,
andy

>
> Agreed.

Actually, Digi-Key's very first product was a digital keyer for hams...
after that for a long while they didn't have much in the way of RF products,
but in the last couple of years they've really come around. They've
been driven almost certainly by consumer electronics use of RF parts,
but as hams we have to learn how to take advantage of all that stuff out
there.

Learning to use all that stuff isn't necessarily automatic! Many of the
parts are available only in surface-mount today. But even though I grew
up on 6L6's and transformers pulled from junk TV sets, I've managed to
make the transition. If a stuck-in-the-mud guy like me can make the
transition, I think others can too!

Oh, yeah, Digi-Key still sells folded-sheet-metal chassis boxes :-)

Tim.

I get interference from a hub in the basement near the rig. Most noise
is on 20 meters. The problem is especially bad if there is an
unterminated wire connected to the hub.

Hi, all concerned:

Looks like the other guy sniped me for $5 on that "HBR16" or HBR12 or what ever it was on ebay. Oh, well. Serves me right for going to sleep at a reasonable hour.

In any case, I won the "matching" c-w transmitter auction, and I'd like to get a receiver to keep it company, if I can afford it.

If anybody wants to sell his finished-or-not HBRxx, send me some info, pictures, and asking-price, privately, please.

Yeh, I started and stopped one in 1958 or 1959, and am suddenly nostalgic for some hollow-state technology again ;o).

TIA and 73,
Dave, N3HE

Go to some hamfests and buy some old radios, transmitteres, receivers, test
equipment, parts, etc and you'll have a ball getting them going and learn.
Not really homebrewing but close and a good stepping stone.
good luck

Thanks, I'll check them out. I used to go to Vetco and Radar a lot.
I went to the old Vetco place (just off 520 past 405) last weekend and
found nothing (I see from the qsl webpage that it has moved, I'll try
to find it). Also, I went down to Radar on Western, saw their sign
saying moved to Bothel, went there, and found as you said that it is
no longer a surplus shop.

I go to Boeing Surplus sometimes for sheet aluminum, and to Everett
Steel and Pipe for mild steel. Hadn't thought of UW Surplus (I used
to work for UW Equipment Inventory Accounting -- wonder if any of the
old gang is still there).

What category is used for components? I see Radio Equipment, and
specific big ticket items.

<< I am attempting to make a code key practice unit. >>

Greg-

The circuits using a 555 may be the easiest to build, but here is another from back in the 60s. Some of the parts were obtained from an old transistor radio and mounted in its plastic case, which was mounted to a piece of wood that also held the key.

Use an audio transformer with a center-tapped primary, with its secondary connected to a speaker. Connect the top of the primary to an audio transistor's collector. Connect the bottom through a parallel 100K Ohm resistor and 0.02 MicroFarad capacitor, to the transistor's base.

The key is in series with a 9 volt battery, connected between the transistor's emitter and the transformer's center tap. A 0.2 microfarad capacitor is connected across the transformer's primary, and a 1 microfarad capacitor is connected between the center tap and transistor's emitter.

If an NPN transistor is used, the battery positive terminal is connected to the center tap, and vice versa for PNP. The 1 microfarad capacitor polarity should match.

Parts values are not critical, and you may get better results or a more pleasing tone by experimenting.

Look under"Business & Industrial" and subcategory of "electronic Components"
Then simiconductors or passive components or whatever you are looking for.
You can get individual types of items or there are some things you may want
to get such as power cubes or asymblies to strip out for parts.

YOu can also find some test gear and tools under the same catagory.

Yes,

Category 5 cable can be run through metallic conduit - to serve as a
pathway.
Specific local or city building codes MAY require this routing of horizontal
cabling.

The EIA/TIA 569 standard covers both horizontal cabling and backbone cabling
for
commercial installation.

For a new hospital in downtown Chicago, where I served as the cabling
consultant
with AT&T Systemax representatives, the horizontal pathways were all
metallic conduit
(Chicago has some of the toughest ordinance and building requirements for
wiring)

Did you use them for small qty ?
What are their prices vs normal prices for still available components ?
(the pb is they want us to give a target price)

I mean, I'm homebrewing a VNA and other toys, and need a lot of different
small qty stuff and digikey, newark, farnell and so on will become somewhat
pricey at the end of the line.

How useful can they be for me ?

Thanks,
Fred.

96. Coil Question

Newsgroup: rec.radio.amateur.homebrew

I had an old regenerative set that was in pretty bad shape so I'm using the parts to build a FET regen set. I just found out the old 2.5 mh choke is open. I know I can purchase these mail order, but I'd like to get this project completed this weekend. Looking through my boxes of old parts, I found an old peaking coil for a tube type TV. The coil is adjustable from .2 to 2.8 mh, at 7 ohms DC resistance. I don't see why this wouldn't work, but thought I'd ask anyway. Will this coil be okay to use??

Thanks

Should be fine. Some impact may be observed depending on where it is to be
used in the circuit. Perhaps as a audio load in the drain circuit??

Is this a coil only, or does it have a paralleled resistor? In TV jargon,
a "peaking" coil is used in the video circuits to achieve the desired
bandwidth and almost always has a built-in resistor in parallel. If yours
is just a simple adjustable coil with no resistor, should be ok.

Well, that's been the direction they have been heading since the Allied Radio days. I know one store owner who would joke that the company push was not "Cell Phones", but "Sell Phones. Anyway, you might make a mention to the store owner. If nobody complains he might be thinking he did a good thing not offering components.

rd=1

The rig being offered is an old homebrew CW transmitter in a National Radio case. Even if you are not in the market, you might enjoy looking at the pictures. I had fun shooting.

This is a collector's item and like the ad says, I like to talk about this rig so don't be shy with questions or comments. In fact if anyone has information as to it's origin I'd love to hear from you.

regards
Jim

You might also examine the original choke carefully and see if you can locate the break. It's most likely to be at an end, or where the choke has been scuffed on the outside of one of the pies. If it's at either of these spots, you can repair it with some small wire, a steady hand, and a good magnifier. (If it's on the outside of a pie, you'll have to unwind a turn or two.) An X-Acto knife with a pointy blade is a good tool for getting an outside turn loose without doing too much damage to the turns underneath.

> >feedback loop. Ok, what are the advantages or disadvantages of doing
this?

At the frequencies we used it would have been necessary to use a prescaler
in front of the DDS. The newer chips seem to be getting up towards a 1GHz
clock rate, so this might be an option

> >What does it do to the phase noise and lock-up time? And what about the
> >spurs?
>
> Spurious are down to normal analogue pll levels.

We found in our design that phase noise was attenuated by the loop inside
the loop bandwidth, but was dependent on the quality of the VCO outside
this. The PLL is sensitive to any spurs on its reference and multiplies them
by 20 Log N dB, where N is the loop division ratio. This applies near the
comparison freq and at harmonics of the comparison freq. So you have to
severely band limit the output of the DDS. If it were in a loop with a
constant reference freq output, you could get even better band limiting, so
this problem might be reduced. Alternatively, the loop filter would get rid
of wideband spurs. Another advantage would be that the computation of output
frequency would be somewhat simpler than with the other appraoch

Does anyone have a pointer to a detailed analysis of this approach?

Richard

It's just an adjustable coil with no resistor. Thanks for the help. The coil is sort of bulky and I wanted to make sure it would work so I could lay the components out on the circuit board.

This has turned out to be a great weekend project. The original radio was hand built probably around '35 or so, but had been hacked up over the years. I'm using the original caps, knobs, vernier, etc and to make a FET version. It's pretty neat, the binding post for the antenna is marked "long wire ant" and the ground lug is marked "gnd". I'm using the original coils (six each) and the bakelite socket.

BTW, I bought the project box from Ten Tec for $6. They are having a close out sale on discontinued enclosures.

Why the parallel resistor? Is it to lower Q and increase the
bandwidth?

A VOX is a simple circuit - no need for microcontrollers
or filters for a basic VOX. I made one with a 555 which
I triggered with a voltage created by the audio. Feed
the audio out of an amplifier to a diode & capacitor.
When there is an audio signal, the diode and capacitor
develop a voltage that triggers the 555. You don't need
a 555 - that's what I had on hand - you can use a
Schmidt trigger IC like a 4093.

Sorry the 17 elements (stated in my request) should read 18 elements on the older style M2 5W/L yagi - Total boom length is 10.461m on the older one as opposed to 10.056m (given on my later M2 5W/L modelling file).
Thanks
Bob

even farthur down the list...

I never bought a whole lot from the shack....batteries,ferric
chloride, and the occasional doo dad were my only big purchases.

Until about 4 years ago I had a shack within walking distance that was
very well stocked in high priced components....like I said I didnt buy
much but they were handy when I somehow didnt have it in one of my
bins.

We did have a regular electronics place here for years....Radio
Electric Supply and it was dingy dusty electronics supply house that
carried everything but they dried up for lack of business about 6 or 7
years ago maybe 8....

2 other places in nearby towns that actually carry electronic supplies
but they are geard more toward cable, computers, and communications
now......any ics or semiconductors will be the 3.00 a pop brand names
like NTE..... no more resistor packs or bulk anything....one of the
stores does not even stock magnet wire and the pros there didnt even
know what it was.

I make my purchases from mouser and electronix express and a few
others....mostly mouser. If you are serious about the hobby you might
as well order 10 or more of the common stuff and make large orders to
save on shipping.

I went to rat shack a couple of weeks ago....they moved to the other
side of town. They had very few components left and didnt knw if they
would restock. They had it all in a big cabinet with bins. They did
have a couple of new rat shack soldering iron stations and some tools
but resistors, capacitors, semicondutors were barely stocked. #
bottles of ferric chloride...I bought 2.

They did have lots of coax type stuff....bncs in many shapes and sizes
and all kinds of "f" coax stuff.

The store was empty and I was immediately accosted by two salesmen who
left me alone when I said I was just loking for electronic parts.

The whole store except for less than 10 square feet is dedicated to
computers and phones....the odd battery selection, the behind the
counter calcualtors etc....but rat shack is clearly a cell phone
dealership now.

<<
This has turned out to be a great weekend project. The original radio was
hand built probably around '35 or so, but had been hacked up over the years.
I'm using the original caps, knobs, vernier, etc and to make a FET version. >>

TH-

I started in electronics as a teenager back in the 50s, by salvaging scrapped radios from the trash behind a friend's repair shop. I separated all the parts and built a sizable collection of tubes, resistors, capacitors and miscellaneous hardware to be used in future projects.

Then I bought a multimeter. I found that many old resistors had drifted high in value, and paper capacitors were almost always leaky. My sizable collection suddenly shrank to a handful of parts!

If you use such old components in your project, I suggest at least checking them with an Ohmmeter. It will save you a lot of frustration.

Most mixers I've seen are not matched to 50+j0. They are simply terminated in 50+j0. Is this the best or optimum termination or does it matter?

There is no "best" or "optimum" termination, beyond the fact that you want a
purely resistive termination. (DUH!). 50 ohms is just the standard value.

That *may* be true, but most mixers are characterized
with 50 ohm (resistive) terminations at all ports.

Use other impedances at your own risk!

This isn't precisely homebrew, but I have a Startek counter, ATH-10.

I think the recent storms have blown the input transistors. Trouble is that they're not transistors, apparently, but little integrated circuits.

I have not the faintest idea of what they are. I think they're made by

Microtek or some such thing, but they seem to be gone.

No great loss. Not a great counter, but it was handy. Shouldn't leave it hooked up during a storm!

Please reply to jwodell@provide.net

Thanks and 73, Jerry, W8GND

A commutating (or reversing switch) type mixer, such as a diode
ring mixer (DBM) will, ideally, present the same impedance at its input
as it is terminated in. This is because, in theory, the output is
always connected to the input, but the phase of the connection
reverses with time. Thus in a downconverting DBM, if the IF is
terminated in 50 ohms, the RF input will have a 50 ohm input
impedance. If the IF is terminated in 75 ohms, then the RF input
will have an impedance of 75 ohms.

In practical DBMs, transformers are used. These are optimized for
a particular impedance, so you will get best performance at the
specified impedance level.

The LO port input impedance has no particular value, being dependent
on drive level, diode turn-on voltage, etc. Typically, it is considerably
less than 50 ohms in a 50 ohm mixer. The manufacturer still advises
driving with a 50 ohm source so that the transformer will be optimally
terminated on at least the primary. I have driven DBM's with voltage
sources and current sources and they will often work OK that way.

hi:

i see a lot of transmitter schems where the VFO's power is switched with the mic or key. and i saw a test where it took 5 minutes of warm up time for a VFO to stabilize.

now, of course a good op will be checking to make sure he's on freq., but aside from reduced current drain on batteries, are there other good reasons to switch the VFO providing it's not leaking into other parts of the rig (if it's a tranceiver) and wreaking havoc?

yeah, this is for a homebrew project. as much as i like the idea of powering down the VFO when it's not needed ...

thanks in advance for any info on this.

Fred -

You can also look at proven designs and schematics
Drift is an issue with tube based VFO - and regulated power supplies
are recommended.

Many schematics and manuals are available at BAMA
Such as the Johnson Viking VFO-122
http://bama.sbc.edu/

Here is another web site for schematics
http://www.geocities.com/CapeCanaveral/Hall/8701/hamfiles.htm

<< i see a lot of transmitter schems where the VFO's power is switched with the mic or key. and i saw a test where it took 5 minutes of warm up time for a VFO to stabilize. >>

Mike-

One of the effects of keying the VFO by keying the power, is a distinct chirp. Another method used in the vacuum tube days, is grid-block keying. A negative voltage is applied to the grid of the oscillator tube, and shorted to ground to turn on the oscillator. This approach would apply to an FET oscillator as well.

Keeping the oscillator running and keying subsequent stages will usually produce a more stable signal. However, it is not unusual for some of the oscillator's signal to leak through and be radiated by the antenna. You can probably imagine a CW tone that gets louder when keyed, but the pitch doesn't change. When such a station is nearby, it is hard to discriminate between the strength of the keyed and unkeyed signal. If you use this approach, you should pay attention to keeping the oscillator from bleeding through. One method might be to key all of the following stages, for example.

that's what i was thinking. key the amps and maybe dump the VFO into a
terminator inside the RFI shield thru a good pin diode switch.

Source record: 34403

I don't think it's ever a good idea to switch the VFO on or off, because of drift. Also, unless the VFO is turned on before the rest of the transmitter and off after the rest of the transmitter, you'll get a bad chirp if on CW. (It would probably be acceptable on AM, and possibly ok on SSB, though.)

Often, a VFO will be heterodyned to the operating frequency. If so, you can switch the crystal oscillator it's heterodyned with. If it's running on the operating frequency, you can pull a trick I first saw W7ZOI do. He switches in some extra C or L when not transmitting, to move the VFO frequency far enough away so it's not a bother. You've got the potential chirp problem here, too (although not nearly so badly as if the VFO is switched from an off state), plus the potential for momentarily transmitting out of band if your VFO is idling there. That can be overcome with timing, making sure the VFO comes to frequency before the rest of the transmitter goes on, and stays there until the rest of the transmitter is off.

In the heyday of the vacuum tube, it was important to keep things simple, since components were expensive and active components (tubes) expensive, large, and power hungry. Fortunately, the bands weren't as crowded, so drift, sloppy keying, and the like were better tolerated. It's quite a trick to mix the techniques of yore and the signal purity requirements and expectations of today. Good luck!

Am trying to repair the (cat chewed) wires of my new titanium headphones, and the usual splicing is not working. They are full size, the wire going to a 1/8 jack. I can undo my repair and hear a low voltage from my supply when applied to the wires. There are a common and either green or red wire on each side, they do not seem to be insulated from one another (the common and colored wire I mean). Any ideas as to what I am missing are appreciated. :)

Hi Alfred,
a mixer is a three-port device. If I remember the theory, a three-port
device can never be matched to the same characteristic impedance on
all three ports. If two ports are matched, the third one is isolated,
so that the network degenerates to a two-port device. Therefore a
mixer with 50+0j ohm RF input cannot have 50+0j ohms neither at the LO
input nor at the output. Some mismatch losses seem to be necessary
with mixers, but they can be easily overcome by increasing the LO
power and more amplification at the output.

I've seen wire like that, but haven't played with it.
The colored wire probably has a heavy varnish coating. It may be
solderable as-is, meaning the varnish melts/burns off at higher
soldering temperatures (750F). See if you can tin the colored wire
with your soldering iron. If not you may have to scrape off the
insulation.

149. Detector/diode question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-08 15:34:23 UTC
From: "Clifton T. Sharp Jr." <clifto@clifto.com>
Message-ID: <3F0AE47F.63C71A31@clifto.com>
Source record: 34415

I was going through my bookmarks when I came upon one about diodes (<http://uweb.superlink.net/bhtongue/7diodeCv/7diodeCv.html>). In his third paragraph, the author asserts:

For RF diode detectors to work, one needs a device that has a non-linear V/I curve. In other words, the slope of the V/I curve must change as a function of applied Voltage. The slope must be steeper (or shallower) at higher voltages and shallower (or steeper) at lower voltages than at the quiescent operating point.

If there's any truth to this, someone please enlighten me. I've always been of the belief that an envelope detector diode would be most perfect if the diode was a perfect switch, i.e. zero attoamps reverse current and perfectly linear forward current (as though the diode was a wire during the forward conduction period). I don't see how a changing slope during forward conduction could do anything other than distort the demodulated waveform, especially on tiny signals.

Oscillators should run continuously for maximum stability. This is true for crystal oscillators as well as VFO's. However it is sometimes desirable to give up
some stability for other advantages such as reduced power drain.

You believe correctly! A diode detector is nothing much more than a rectifier and should be characterised accordingly. Curvature of the forward characteristic has to be lived with and is not something generally to be desired. There are exceptions to this where the law of the initial curvature is employed in certain instruments but not usually in demodulating an AM signal.

However, with very weak signals a small degree of forward biassing is sometimes employed to obtain the greatest recovered audio. This comes about because the positive peaks are driven onto the greatest slope while the negative ones, which would normally distract from the charge on the load capacitor, are placed on the flatter part below the bias point and so not recovered so well.

Cheers - Joe

That might be true for lossless, linear networks (I honestly don't know), but it's a simple manner to create a lossy three-port network that presents 50 ohms at all three ports. For example, a 16.67 ohm resistor from each port to a common point, or simply a 50 ohm resistor at each port with no internal connections between ports. A mixer is nonlinear besides having loss, so there's no good reason to believe that it conforms to rules that apply to lossless, linear networks.

The post appears to have generated some interest. Specifically, how does the match/mis-match, as the case may be, affect one of the (perhaps the) most important paramater which is the input 3rd order intermodulation distortion level? And what about loss?

In other words, will a mixer (not limited to diode mixers) operate equally well into any termination as long as it is R+j0?

If it is like magnet wire enamel, soldering heat will not always
remove it. You need to either scrape with a razor blade, or use a
heavy-duty chemical made for the purpose. The warning label on it may
have you using a razor.

160. Small 2M crystal FM design

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-08 22:56:40 UTC
From: rpg@hotmail.com
Message-ID: <4ef33040.0307081456.36da045@posting.google.com>
Source record: 34426

Hi, I'm looking for a small, 2m FM fixed frequency TX design for a backup telemetry link on a model craft. I've seen designs based on discontinued Motorolla baby-monitor ICs, but simple varactor/tripler designs seem less common. Weight/size are important, and I'd like output around 1-2W. Duty cycle will be fairly low. There is 4.8V or 12V available already; 4.8V is likely to be noisier, as it drives the servos. 12V is prefered.

What I was thinking was ~48 Mhz crystal oscillator with varactor, fed into a tripler, then a bandpass, then into an amplifier (RF transistor?)?

I've seen a number oscillator designs floating around (handbook and otherwise), but I don't know how to find out what's most appropriate. Any suggestions, designs I've missed, books to read, etc? Something like the Ramsey FM6 (preraid)?

Plan B is to find another HTX-200 or similar, pull out the guts, and use that. :) But I'd rather have something I can lay out myself.

Thanks,
R C

Dude, you and they are talking about the exact same thing.

Think about the V-I curve on an ideal diode. Observe that, if the diode is
reverse-biased, no conduction takes place. In principle, you can crank the
reverse voltage up as high as you like, and STILL no conduction takes place.
(In practice, you run into avalanche and zener breakdown.) If the diode is
forward-biased, the diode conducts like crazy. There is a CORNER in the
curve, i.e. a change in the slope of the V/I curve, at NOMINALLY V=0V.
(Actually, V=0.7V for silicon, V=0.3V for germanium, V=1.7V for red LEDs,
about 2.2V for yellow, about 2.4V for green, and so on and so forth...)

All, thanks, I am up and running again. I was also given the following hint
regarding enamel

Hint for removing enamel:
- Heat it up with a match or cigarette lighter;
- When hot, quickly sink it in alcohol.
The enamel cracks. Just take it off with your fingers.

Ricardo

164. Re: RF mixer termination

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-09 04:53:00 UTC
From: Jim Pennell <NoSpam@killspam.com>
Message-ID: <beg73hmq1@slb9.atl.mindspring.net>
Source record: 34430

My understanding is that diode mixer IF ports do more or less match the RF port impedance of 50 ohms when each diode is turned on hard from the LO drive. Granted, it is "approximate" but a good general way to look at the mixer IF port impedance.

The reason to broadband terminate the IF port as 50 ohms is to provide a "matched" termination for the RF signals and all of the other RF type components that show up on the IF port.

A mismatch on the IF port will tend to reflect the mismatched signal back into the mixer diode junctions and depending on phase and so on may, and usually does, result in degraded dynamic range and possibly higher mixer loss too.

While it is not a truely matched load for the LO signal impedance, it does absorb most of the mixer products and so a non-reactive 50 ohm load is the best "generic" load impedance for most mixer uses.

In certain circumstances, one can calculate and match the actual impedances but this is tricky and prone to errors so using a fixed broadband 50 ohm load is usually the simplest way to get good performance.

Motorola did a number of one chip FM TX ICs, - they are cheap and widely available and produce about 50mW output which can be use to drive something like a 2N3866 output stage (I only give that device number as I have one in the junk box!)

Daft as it seems, that actually sounds quite promising! I thought my
tube was dying too, until someone showed me how to set up storage mode.

The optimum intensity setting in storage mode is lower than in normal
mode, and the setting is *very* critical to get a clear and visible
trace with no flare. It should be just below the point where the
background intensity starts to increase very rapidly... but a gnat's
whisker below that, the trace itself is too dim to see! You'll never get
the same contrast between a bright trace and dead-black background that
you do in normal mode.

Keep on experimenting, and you may well find it's OK.

I had a rig in which I kept the oscillator running on key up. "VXO 6 watter"
from "QRP Classics". Great rig. The "backwave" never caused difficulty in
copying. I got about 5 W out (keydown) and about 15 milliwatts out (keyup!)
This provided some fun: If a station gave me a good report, I'd ask if they
could hear the REALLY QRP oscillator on key up. Many could!

It can actually be much simpler these days using a minicircuits vco (50R output) and a pll chip, not a lot else to it really.

10mW would give you a fair old range line of sight.

Stick a minicircuits ERA 80mW device (4 legs, 50R in, 50R out) on the output of the vco if you want a bit more umpf.

Just as easy on 70cms or the unlicensed 458MHz ISM band, same for 23cms and 13cm or 2.4GHz ISM band. It's SO EASY these days with the building blocks you can get.

Clive

I'm not sure I was clear on my question. The only nonlinearity I want in
my detector diode is the noncontinuous function

| Vin when Vin >= 0.000000 micronanofemtoattovolts
Vout = |
| 0 when Vin < 0.000000 micronanofemtoattovolts

...while the author seems to be saying that the nonlinearity which exists
just above the barrier voltage is essential to detection. He does say,

"The slope must be steeper (or shallower) at higher voltages and
shallower (or steeper) at lower voltages than at the quiescent
operating point."

Given my perfect diode and (let's say) a 0.25V peak signal, I contend
that my output envelope will be an exact reproduction of the input
envelope; but (see his graph #2) his required nonlinearity will seriously
distort the output envelope.

He seems to be saying that without that, you can't demodulate the signal.
I assert that without that, I demodulated it better than he did.

And that removes a lot of the nonlinearity (especially by no longer
chopping the bottom 0.2V off the input signal). But this author seems to
be saying that detection can't work without that nonlinearity.

Am I missing the contradiction? Say you have a quiescent operating point of 0V. An ideal diode would have an infinately high slope above that point and a 0 slope below that point. Or vice-versa. That seems to fit the given statement.

Real world diodes have differing ideal q-points and variable slopes. And most of the other articles seem to be aimed at getting the most out of such diodes.

>

I think your perfect diode analysis is correct. I think the only nonlinearity the author requires is around a q-point. I don't get the impression the author requires a diode to have a variable slope characteristic at other voltages.

Yes sir,

In the early days of networking, I had to install and support a WIDE variety of networks and
physical media (and a few different file server OS - but largely Novell !!)

In addition to the original Token Ring 4 Mbps and Thick and Thin Ethernet (10-Base-5 and 10-Base-2)
Altos Server and original 3com Net (Thinnet based)
Novell's S-Net
Proteon's 4-Net and 10-Net (10 Mbps 10-Net was not adopted - later IBM 16 Mbps was)
G-Net (1 Mbps)
Omninet (for Apple II)
ARCnet Token-passing (PC and old Datapoint 8-bit processor version)
Sytek / IBM PC Network (used 75 ohm CATV cabling)
Appletalk for Macs
AT&T StarNet (another 1 Mbps)

and others from Novell lab classes when Ray Noorda showed up and signed your certificate!

Today, the company I work for is owned by the US patent holder for Token Ring

... who said the world is small?

Source record: 34299

Hi:
I am having a problem with a "Simple Receiver for Beginners". It is from a design that was featured in an old (1981) ARRL handbook. It is a DC receiver, looks like alot of fun, but it isn't fun now.
Here is the problem.

1) No oscillation! I can't find it (the VFO) on my DX-398 receiver at all, or on my Radio Shack freq counter.
2) The power (+ side) electrolytic is supposed to be a 500uF, 16 volt. I am using a 470uF 35 volt. It gets really hot!! Short somewhere?!?!?!

The VFO is REALLY simple, it has one transistor and about 7 other parts. I can't seem to see what is wrong, and I have tried.

I would sure appreciate some Elmer'ing here!
ANY help would be much appreciated. I have the above mentioned tools at my command, a multimeter, and an old Heathkit "scope. (which I really don't know how to use.

Any chance?
Thanks in advance,
Tom

Check to be sure that you don't have the
electrolytic in backwards!

Source record: 34306

Tom:

The hot cap has two likely possibilities: either the cap is shorted internally (an ohmeter check will show leakage) or you have bad diode(s) so AC is being applied to the cap. An ohmeter will show the diodes as bad.

Of course a wiring error could also be involved, but I am assuming you have double checked that.

If the cap is running hot you probably don't have the correct voltage for the VFO, and correcting it may solve the other VFO problem.

It's a good idea to build things in stages, testing each stage as you go.

Try disconnecting everything from the power supply and sort that out first.
The capacitor shouldn't get hot.

Are you using a tantalum capacitor? If they are inserted with the wrong
polarity they will get really hot ... sometime will actually burn.

> ... microwave seemed good until i head about the costs ...
> ... line-of-sight,

Now this will sound a bit strange, but there are several methods of communicating up to about 1 mile WITHOUT a licence. Radio Amateurs will try to tell you that you HAVE to get a licence to transmit. This is not so (and I am a radio ham!). Some methods below are omni-directional, but remember that most antennas are not omnidirectional. The only omnidirection antenna I know of is an "Isotropic" antenna, and that is entirely fictional, just like the square-root of -1, Father Christmas and DXing via a VHF repeater.

1 - Hammer two copper posts in the ground. Attach a wire to each and connect to them the output of an amplifier. Connect a modem tot he input of the amplifier. You will need to set the modem to "leased line" operation so it doesn't look for a dialling tone. The receiver station, 1 mile away, is two copper posts hammered intot he ground and connected to a small-signal amplifier input. The output of the amplifier is the input of the second modem. You should easily get 1-mile if both have the rods about 10 meters apart.

Disadvantages - It doesn't work too well in the dessert (I have tried it just outside Jeddah on the old Makkah road). It is not too brilliant in well built-up areas since you also pick up a load of mains hum. It may not be a problem for a modem, but it sounds bad on the ears. A filter?

Advantage - it DOES work well underground, if you can fid a place to hammer the electrodes. When experimenting in "Swildens Hole" in the Mendips there was a river following the cave (a stream, actually, but it seemed like a river when 1/2-way up an electronladder and it's pounding down on your helmet) and the electrodes can just be dropped in the water. Most caves just have rock.

2 - Modulated Laser transmitter and photocell receiver in torch / headlamp reflector, but this is quite directional. The laser can be modulated quite rapidly by bouncing it (reflecting) from one of the side electrodes of a Quartz crystal. They are plated with copper and allow you to modulate up to several 10's of MHz. The laser only needs to be a low-power 5mW or so visible-light laser. I used a 2mW to get over 100 feet this way.

When I tried a 25mW laser I had the police round (Grunty Fen, Cambridgeshire, 1988 - G8TGL). They said I had "crossed communication routes", but I was shining the thing on Ely Cathedral clock face (3 miles away), so I suppose I deserved what I got. Incidentally, I used this method to make a 4' square oscilloscope - HiFi driving speaker cones with mirrors mounted on them. Beam projected down garden and reflected by by mirror. HiFi channels driven from Apple IIe computer.

Disadvantage - not exactly omni-directional, or anywhere near it.

3 - Modulated infra-red LEDs. Can be made about as amni-directional as a 2-ele Yagi and you can modulate with a whole radio spectrum, up to about 10MHz. This means that instead of antennas you can transmit using your own private radio spectrum. Great for teaching boyscouts and newbies to hamradio how to operate a transmitter or training morse code. Use ordinary commercial/homebrew receivers and QRP transmitters. You can even add a part of the radio spectrum as background noise by connecting an antenna to wideband amplifier and modulating another IR LED. This method is great since the only radiation is modulated light for which you do NOT need a licence.

Disadvantage - if you shine each LED on the ceiling you can cover a whole church-hall using, sensitive receivers (mine was FRDX400) and each LED transmitter is a bank of LEDs - but it is crap outdoors, since you cannot see IR so you cannot focus or point the beam.

4 - Magnetic induction - If this were in reality "radio" then Mahlon Loomis would have been the father of radio in 1868, NOT the spaghetti-basher Maccaroni in 1904orsomethinglikethat. Basically, if you pass a DC current through a wire, you get a momentary DC current induced in a parallel wire, since the two are coils (transformer principle).

In 1970 (RAF Locking, and Tern Hill) I listened to my HiFi whilst in the bath in an RAF barrack block. The distance from my room to the "ablutions" (millitary talk for bathroom) was about 150 feet. I took a 20-foot length of 10-pair telephone cable and cross-connected the ends so I had a 20-turn coil of wire about 6-foot in diameter. I connected the two ends to the two speaker terminals of my HiFi and the ground to the centre-tap.

The receiver for this was a TV Line-Output transformer ferrite core (they come in 2 halves) stuck (glued) end-to-end with a rod of ordinary MW aerial coil between. In effect I had a 18-inch long ferrite rod; the middle bit thin. I wound about 600 turns of wire on the middle bit and connected that to a transistor amplifier. Voilla! I heard my stereo (now in Mono). Perhaps you can connect this system to modems? Dunno about the range, I had a VERY strong signal, but I never tried to exploit the range above the required 150 feet.

Dissadvantage - In those days ordinary hearing aids used valves and had a magnetic microphone. The corpral on the floor below me was megga pissed-off since he did not like Jethro Tull and "Groovin With Mr Bloe", but he never found out it was me, thank God! Today there are other magnetic thingies around. You may have other problems, but I am sure that the old corpral from Turn Hill is now dead. He was an "old codger" over 30-years ago.

Finally,
5 - Broadband - Get yourself a broadband connection from your local ISP and connect to your home computer. You should know the IP number. You could even try putting all your info on a single hard disk and taking that around with you. But these simple solutions are often not the most impressive when showing-off to visitors.

http://w1.859.telia.com/~u85920178/

Very best regards from Harry -

Try contacting ARRL for corrections to the article. I built a DC rcvr from about that time frame and it did not work. The ARRL sent corrections to the schematic and there were a lot!!

Hi, You must clock it in/out using the digital i/o lines of your
processor (or i/o). |It is easy to build in formware, using any
processor. I think you must first look at what you want to do with
it. I have made many of those things, but not with
exactly this part. Contact me if you want more info,

Regards,

Pieter Hoeben

was there any shielding around the VXO or a terminator to keep the
leakage down?

Electrolytic capacitors are polarized. Probably you reversed the cap and
smoked it.

Start by looking at the voltage at the electrolytic cap, and see if you in
fact have voltage or not.

and when you run an electrolytic at a different WVDC than it's rated at,
you can't be sure the capacitance is the same as marked on the can. but
it should still filter and not get hot. you'd think something else would
heat up if there was a short. should draw excessive current. unless it
blew something and is now an open, then the cap shouldn't get hot any
more.

good idea. he (OP) said 500uF cap. never heard of one. some article!

the disconnect the load and shoot the supply idea is also good. then
check the load (circuit for shorts b4 reconnecting the supply.

No, it won't.

It will however supply the wrong polarity of DC, which could indeed
cause these symptoms.

I would think some other semiconductors might be running rather hot too
if that were the case.

that must be why i have a hard time finding the MC3361 or maybe it was
the 3362 used in RC aircraft receivers. Motorola sold the Mosaic line
and it's hell trying to find 'em. yeah, i know. they're receivers. but
it's still from the Mosaic line.

what suppliers do you suggest? i used some parts search engines and the
number in stock varies from day to day.

MC2831A, MC2833, MC13175, MC13176. i got samples of one of 'em a long
time ago, but as i said in another post, motorola sold the Mosaic line
to either Micro-Semi or On Semi. either way, it's hard to pick a chip
for an app without the data sheet. before you ask me to scan and e-mail
them to you, tell me how to get my HP scanjet 3c to run on w2k and XP.
HP doesn't even know how to make work on win9x. the website has software
for 9x, but they fail to mention that you have to install DOS software
first. That doesn't work with NT systems like 2k/XP.

re: Want EF Johnson Two-Way Radio Mic for spare(s)

Hello there,
-
I'm looking for at least one or more spare mics that work on the common EF Johnson two-way radios. We have a 483MHz band, Johnson Radio in service at a local Vol Fire Dept. I donated my last spare mic yesterday... let's just say they are a bit rough on them.
-
The older EF Johnson 8615 and similar type 800/900 trunking radio mics swap right in to this rig. It's uses the now standard modular plug/jack setup. Your old unused trunking radio seems to be a good source of mics for this vintage 483Mhz unit.

If you have a dead or spare radio around with a possible working mic, I'd love to try and beg/buy/swap you out of it. I'll pay a reasonable price for a mic and or trade you for some other mic I might have. I can also trade you for some other item or service I might have to offer.

Thank you for reading this post.
Please take the NOSPAMPLEASE out of my Email header and drop me a reply when you can.

cheers
skipp

oops. right. 1 diode backwards in a full wave (not a bridge) rectifier
would short the xfrmr.

- just a quick question:

how hard would it be to wire up a third-party mic to an htx-252?

the htx-252 pinouts are available... AFAIK, no audio is sent to
the 'standard' mic...

oh, and i don't care about DTMF, although i do have a spare
yaesu DTMF on hand...

if anyone has done this i'd appreciate a tip or two!

tia!

210. Problem with. Astron RS-50M Power Supply

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-10 18:56:54 UTC
From: TLNixon@mchsi.com
Message-ID: <g0drgv8ohhu7celo0kg5gb8qfceecfqmo3@4ax.com>
Source record: 34326

With the gear hooked to the supply, even with it turned-off, when I turn on the supply, the voltage transient cleans or erases the programming in the radios. It's not the radio, as it does it with 2-3 different ones.

Does anyone have any idea how to solve this problem, or if a faulty component might be causing it?

I've worked on more than few of these supplies, and have never seen this problem before.

I've E-mailed Astron, and did not even reply.

If you're using a diode bridge like most people do these days, and the diode bridge output terminals (+ and -) are reversed, the filter capacitor would get hot and the receiver wouldn't work.

As others have pointed out, an electrolytic capacitor with reverse voltage applied can catch fire or explode. Be careful when troubleshooting while the capacitor is unhappy. When you do find the problem, it would be a good idea to replace the capacitor.

i've had a couple explode, usually from overvoltage from a shorted
series pass reg, i think. nice thing about (some? most?) electrolytics
is that X that's scored into the top so it blows straight up. i'm glad
my face wasn't over top of it, though. even with safety glasses, it's
not something i'd like to experience.

The VFOs in all my old Txs stay on all the time. I use a simple RIT
circuit to move the VFO off freq on receive and key it with either
plus or minus depending on the way the rest of the Tx is keyed.
Works neet...

Source record: 34329

When you have a problem like this, and have done some good work so far (determining that a cap is hot) it's time to stop guessing like all the well meaning guys here are suggesting, and find out what is wrong.

First thing you do is get your voltmeter and set it on a dc scale, and measure the voltage and the polarity of the voltage at the top of the capacitor. If it isn't close to what it is supposed to be, snip off the wire to the load (the vfo) and verify that it is still not right (the vfo could have a short). Then snip out the cap and see if the voltage coming out of the diodes is what it is supposed to be, etc. etc. In other words, use good common sense and troubleshooting techniques - no guessing. There aren't many circuits that are easier to troubleshoot than a power supply.

I recently took a never used tiny little electrolytic out of my capacitor drawer for a project and soldered it across the vcc (+12 volt) line and my voltage went to zero. I went back to the glob of capacitors and tested about 5 more and all were ok, so it can happen.

FIRST, check what you true voltage output (e.g. 12, 13.8, 15 volts) is from the Astron
RS-50M (may be visible on the front panel meters -- but double check with a good VOM or DVM
on the output (with an without load)

The crowbar circuit usually trips somewhere above 15 volts (as I remember)
Follow-up with the schematic and "how an Astron works"

A voltage transient tells me to check:

LM723 for proper operation (common problem)
Filter capacitor
Q2 transistor (for proper operation) driven from the LM723 that in turn drives the
base of the pass transistors

Well, thanks for the part numbers. It does help since Motorola,
Microsemi and Onsemi all deny knowledge of these chips existence (at
least on their web sites). :) I'll note Ocean state electronics has
datasheets for most of those, and appears to stock some. I've never
dealt with them, but they came up on a google search. :)

I'll keep an eye out for these or similar at the BRATs hamfest later
this month, thanks.

The reason I asked for higher output is that this is to provide a
backup data link to a 1/2 Watt ATV transmitter.. it needs to have more
range than the ATV link, and use a small omni antenna. I know a 2m
TX's bandwidth is smaller, thus more efficient, but I do think I need
more than 50 mW.

R C
KG4MVB

Re: Scanner: Dunno if it helps.. if you have an older box, toss a
linux distro on there; SANE supports the 3c and the network scanning
worked pretty well last time I set it up. It'll take some setup time
(more if you've never used linux), think about it; USB scanners start
in the $50 range..

First, verify the problem. To do that, connect a switch
between the Astron and the equipment. Turn the supply on,
wait one minute, then turn the switch on. If you still have
the problem, it's not in the supply. If it eliminates the
problem, you could try adding an automotive relay in place
of the switch. Energize the relay from the 13.8 volts -
it will give you roughly 8 milliseconds delay between the
time you switch the Astron on and the time power is available
to the equipment. That doesn't fix the transient problem, but
it does bypass it. Another solution that doesn't fix the
problem (at its source, assuming it is a supply generated
transient) but does bypass it is a transorb diode rated at
15 volts, connected across the supply 13.8 v DC.

If the supply is creating transients causing the problem,
and you want to fix it at the source, you could try bypassing
things to ground with a bunch of .01 caps.

dude, thanks! i have an old 90MHz HP XU that still has a slot for the HP scanjet card. i use it for a Linux file server at home, just 'til i replace it with a better box. i imagine any box would work.

i know scanners are cheap, now but when i bought this big old flatbed, they were $1200 and i've hardly used it. can't just toss it.

> What kinda of amp and what are you connecting to the amp ? What kind of
> modem ? I can understand the principle of this but what equipment are we
> talking about? Might seem dumb but had to ask!

Not at all a dumb question, only politicians ald solicitors ask dumb
questions.
HiFi amplifier, perhaps around 50 watts RMS is about right for one or two
miles.
The modem would be an ordinary old-fashioned modem that is connected between
a computer serial port and a telephone line. In days of old, people used to
connect to bulitinboards (BBS) via a modem and anyonecould have a BBS by
just connecting a moden between the telephone line and computer, then
running BBS software. A bit like a packet repeater. Most modems had several
modes, such as "leased line". This facility allowed two modems to have a
permanent and dedicated landline betweent he two, for example a multichannel
(perhaps 960+)telephone MUX link. These lines have just 600 Ohm audio + E&M
signalling. The "modern" 56K PC internal modem may not be suitable, but a
9K6 or 28K external modem (using todays terminology) would be fine. Even a
"Baycom" modem or "Hammcom interface" would work, if the right software were
available to drive it.

> Is there such a thing as a reciver station for bi-directional
communication
> ?! Again i don't understand the term of 'modem' here.

Modem is short for MODulator / dEModulator and it is nothing more than a
data / audio interface for connecting together the serial ports of two
computers. Serial data -to- audio tones -to- serial data. With this you can
connect two computers together in such a manner that communications software
can be used to share services between them, for example:
- slow (modified) LAN connection
- FX (DOS based) file transfer software
- Laplink (Windoze based) file transfer software
That which I first used was written in GW-Basic and took me about 40 minutes
to work out the code. Gave me a "DOS" window tot he distant computer.

Hope that this helps. BR MOTUASROALB (Alias Harry)

> PSTN uses a single twisted pair, how can you seperate I/O from these? I'd
> like to give it a go.

Use two split-secondary transformers. In that way you can build a "Hybrid"
to isolate TX from RX. Besides that, when I first experimented with this the
modem I used was a "MyCom" (Jap pirate copy from the ME) that used 300
bauds. The TX and RX FSK tones were different so a little breakthrough was
acceptable.

My experiments using 9K6 and 28K modems only used a "field telephone line"
so the problems were somewhat fewer. I presented the idea, if you want to
try it then you can grab the ball and run with it. I don't intend to do any
more experiments with this, but I and I am sure many others, would be
interested inthe results of your experiments.

Ok, so this thread has now become a discussion about the meaning of the
prefix "OMNI". So if God is only OMNI-potent and OMNI-present, then in which
planes does she not have influence or presence?

Ok, I know my theory. According to the "official" definition, an
omni-directional radiates or receives equally in all directions in only one
azimuth. An isotropic antenna is a hypothetical antenna that radiates or
receives equally in all directions. Isotropic antennas do not exist in
reality but are meant to represent a convenient reference antenna for
expressing or comparing the directional properties of real-world antennas.
But you know exactly what I meant.

OK, if you don't like like those ideas about mobile phones,

1) Modify a ï¿½25 pair of PMR transceivers, should do 3km.

or

2) Buy a pair of ISM transceiver IC's, e.g Chipcon, I got about
400m at minimum power (0dBm) cost about ï¿½8, or look into low power
radio solutions 433MHz modules.

Simon

228. question about 2SC2509 RF driver

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-11 17:09:41 UTC
From: Joe LeKostaj <joe@falseaddress2003.net>
Message-ID: <joe-D52398.12094111072003@news.covad.net>
Source record: 34344

Can someone please check something for me on a 2SC2509 transistor if you've got one lying around? This is the RF driver used in the Kenwood TS-120/130 and probably others. I'm repairing one of these PA assemblies and trying to determine if the two transistors I've got are good or not.

Using the diode-check function of a digital multimeter, all the junctions test OK except for one oddity: there's conduction with the + probe on the emitter and the - probe on the collector (and base open-circuit). Can someone tell me if a new, unused part exhibits this?

I would normally consider it a bad sign, except:
- All the other junctions show the normal expected operation.
- DC beta checks OK (around 65) with a Heathkit transistor tester.
- Both parts test exactly the same. (unlikely if they're damaged.)
- Seems I've heard somewhere that this type of transistor with the emitter connected to the mounting tab (as oppposed to the collector) required an extra metallization layer which might account for the emitter to collector conduction described above.

Would appreciate any help with this. Reply either to the newsgroup or to K9LY at arrl dot net

Tnx & 73,
Joe

> I assert that without that, I demodulated it better than he did.

I think you and the author are saying the same thing. Consider that in your ideal diode case, the quiescent operating point is zero volts. Above that, the slope of your diode is infinte (zero ohms) and below that it's zero (infinite ohms). The author is suggesting that you do NOT need it to be so sharp, and in fact, I find that I can detect RF down to below 100 microvolts or so with a Schottky diode designed for zero-bias detector service, though the output voltage is very tiny down there. If I could buy one of your perfect diodes, 100uV (RMS) of RF would give me around 141uV of output, instead of the sub-microvolt I do get. The low output is the result, of course, of the fact that the diode dynamic resistance at -140uV is only very slightly different from its dynamic resistance at +140uV.

In a real diode, the change in slope is gradual with no sharp corners, but if you could find a diode which looked like, say, 1000 ohms in the reverse direction for all voltages and 1000.1 ohms in the forward direction, it would still work as a detector, albeit a poor one.

Cheers,
Tom

230. Re: Problem with. Astron RS-50M Power Supply

If the Astron overshoots, you can verify it with an oscilloscope. If indeed it does that, you can modify the circuit to reduce that.

Why are you using a 35 Ampere power supply for such a small load? It would be better to use a lower current rated unit. I use a 20 Ampere unit and have no such problem.

Looking at the diagram, you can put in a capacitor across the reference voltage at the IC to reduce the turn on speed.

On the other hand, it's possible the problem arises due to too slow a turn on of the supply. You can do things to improve that also. Also, the supply may be oscillating. Try connecting a dummy load of, say, a few amperes across the output. An automobile headlamp can work for that.

Best to verify the actual cause with an oscilloscope before starting to make modifications.

One kind of AM detector is the ideal diode, which is "piecewise linear". That is, a closed-switch for one polarity of the input signal, and an open-circuit for the opposite polarity. For large signals the ordinary diode approximates this ideal diode. For small signals the ordinary diode detector has some defects.

Another kind of AM detector is the square-law device. A real diode that is correctly biased approximates this for small signal levels. In some applications it is preferred. There are tube nd transistor circuits that are accurate square-law detectors. These circuits provide detection plus audio amplification.

A square law detector follows the rule:

i(out) = k [v(in)]^2

If an AM signal at RF frequency Wc and audio frequency Wm is applied:

v(in) = K [1 + m cos(Wm t)] cos(Wc t)

the output current i(out) contains the term cos(Wm t), the baseband modulating frequency. It also contains a second harmonic distortion term cos(2 Wm t), plus other terms that can be filtered out.

If m = 0.30 (30 percent modulation) then the second harmonic distortion is m^2 / 9 = 0.01. This is a percentage distortion

D = [0.01 / 0.3] x 100 = 3.3 percent.

For some applications this method is acceptable, sometimes even preferred. The square-law circuit can also be used as a frequency doubler.

Notice the "m" after "dB". It's a standard unit referenced to 1mW (to which
the "m" refers). 0dBm is simply 1mW.

If you happened to insert the diodes in the fullwave rectifier reversed, you will have negative voltage at the input of your filter instead of positive voltage, and the input filter cap will conduct, and get hot (in a fullwave rectifier supply). If that happens you hope the filter cap DID short the supply to ground instead of passing the reverse polarized voltage on to other solid state devices! In time this will be rough on your transformer, too.

You might want to recheck all the polarities of the diodes.

Dick

The 2SC2509 is popular bipolar RF transistor used as a driver transistor for
amatuer transceivers
(Kenwood TS-440) OR as the final transistor for low power (Yaesu FT70) and
CB transceiver usage.

The only time I have seen caps get hot is when they are in backwards. If there is too much ripple voltage, the cap can get warm. I would double check the wiring. I am not sure what method you used to make the VFO, so everything is up in the air.

```
Junkbox Surplus Parts for Sale as of 07/10/2003
===============================================

NEW ITEMS

I have 200 excess pcs of 5.000 Mhz crystals. These are the miniture
crystals like you see in the latest QRP Quarterly. Tiny round
crystals with two wire leads, I think I've seen these in watches.

20 for $2.50

I have 400 pcs of 102J (1000pf) Shinyei ceramic caps rated at 630
VDC. These are in bags of 200.
$5.50 for 200 including USA shipping.

I have surplus 50K 1 Turn linear taper pots, about 25 each. These
are chassis mount pots with the nut. About the size of a nickle, and
about 1/2 inch deep with a 1/4 inch shaft about 1/2 inch long.
5 for $5.00 including USA shipping.

2.5/5.5mm Coaxial Power Jacks for PCB insertion or Manhattan install
10 for $3.50

285pf Green Square Plastic Cap, PC Board Insertion 10%
100 for $4.00

220pf 5% 63V SMD Caps - Surface Mount size is 0806
50 for $1.00 PLUS you must send a SASE for return.

Odd Items
============
9.8304 Mhz Crystals, 1/4 in tall - 20 for $5.00
27mH inductors with radial leads - 25 for $3.50

Caps - All new, old stock. No pulls.
====================================
All caps now 50/$3 or 100/$5
====================================
8pf NPO Ceramic - Loose
11pf NPO Ceramic - Loose
12pf NPO ceramics on tape
22pf Kemet Ceramic Caps, 200v, 10%
150pf ceramics, 100v, 10%
470pf Ceramics on paper tape, rated 5% (NPO)
560pf Kemet Ceramic Caps, 200v, 10%
1000pf blue mono caps, 10% 100v
```

3300pf Kemet Ceramic Caps, 100v, 10%
.01 uF ceramic caps, 10% 100v brand new by Kyocera
and
.01 uF ceramic caps, 20% 50v, new old stock, not used
50/2.50 100/$4

Voltage Regulators
==========
L7805ACV voltage regulators TO220 case. 10/$5 or 15/$7 100/$30
LM7812 voltage regulators. TO220 case. 5/$4
LM317T Adjust. Positive Voltage Regulator TO220. 10/$5.00 or 15/$8.00
LM78L62ACZ Volt(6.2)regulators, TO92 format 5/$3.00

Transistors - New Parts - No Pulls
==========
TP2222 plastic TO92 NPN (House brand 2N2222)50/$4 100/$7
2N3904's plastic TO92. NPN - 50/$4 100/$7
2N3704's plastic TO92, NPN - 50/$4

Op AMPS
==========
LM386N-1 - Audio Amps 5 for $3.00

LM741CN - Single Op Amp, 8 Pin Dip, 6 for $3.00
http://www.hep.ph.ic.ac.uk/~hallg/Instrumentation/Data/LM741.pdf

Diodes
======
1N4148 - You always need these. 100 for $2.50

Let me know if you're interested. All prices are post paid to the
USA, unless otherwise noted. I will ship to non USA addresses but we
need to discuss the shipping charges first.

241. Re: help with homebrew receiver!

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-12 04:53:23 UTC
From: TC Dufresne <tdufresne@neb.rr.com>
Message-ID: <CINPa.205761$jT4.3907021@twister.rdc-kc.rr.com>
Source record: 34257

Everyone. I fixed the VFO. Its a good news/bad news thing.

Apparently my MPF102, the heart of the VFO, was either shorted out or not working. I removed it and replaced it with another.

Good news..Cool! Now I have a good VFO in my receiver, I can hear it in my trusty DX-398. I adjust the RF coil so its low end (with maximum capacitance on my Hammerland 1-10pF variable capacitor-fully meshed) is around 7.00mHz. When I go to minimum capacitance (no meshed), I hear it only around 7.060mHz. According to specs, I should get a range from 7.00 to 7.2mHz.

Why do I not get more range? As far as I know, all caps are up to spec as called for.
Do I need to add/subtract capacitance somewhere?
Thanks again,
Tom

Son, that's called a Selenium rectifier.

Goddam newbies. :)

> be 0dBm, where 0 is a reference to what power level ?

Decibels are a logarithmic unit.
Any number raised to the power zero is 1

therefore the log of 1 is zero.
decibels are tenths of a Bel
a Bel is the log to the base ten of a power ratio

in the case of dBm the reference power is taken to be 1 mW one milliwatt.

Therefore the ratio of any measured power to 1 mW is the thing that we want.
You have 1 mW of power so the ratio is 1mW/ the reference power 1 mW = 1

the log of 1 is 0
ten times the log of 1 is also 0
therefore 1mW = 0 dBm (the ratio to the reference power is 1)

that is: the power in which you are interested is equal to the reference
power of 1 milliwatt.

I hope that confuses you, :)

Theory of LM723 operation (courtesy David Metz):
[An Astron schematic, when reading, is helpful]

The LM723 is a twenty some year old IC designed to be a universal voltage
regulator.
Being cheap and well understood it found in most of our bench supplies and
is the core of the popular Astron series.

Any bench supply consists of a transformer with a secondary of about 18
volts AC,
a rectifier block and a filter capacitor. With no load, the DC voltage
across the terminals
of the filter are going to be 18 to 30 volts.

Under load the voltage will sag due to the impedance of the secondary of
the power transformer. If it sags too far, the supply will loose regulation
and it will pass 120 Hertz ripple (hum) to whatever you are powering with
it.

Since the voltage across the filter capacitor can vary wildly as the load
changes
we need a method of regulating the voltage. The work of regulation is done
by
the pass transistors (Q2 to Q5). They in turn are controlled by the 723
regulator.

Lets look at the 723 in a little more detail now. Note that it has its own
filter power
supply made up from diodes D1-D4 and filter capacitor C2.

The 723 has its own internal highly regulated voltage reference supply (pin
6).
Internally the 723 compares this reference voltage to the output of the
power supply.

Voltage adjustment pot RV1 sets the "ratio" of the reference voltage to the
output of the supply.

This sets the output voltage from the supply.

The output of the 723 is pin 10. This voltage drives the base of Q1. Q1 acts as a simple amplifier to increase the current available to drive the current hungry bases of the pass transistors.

As the load increases on our power supply, the voltage from the wiper of RV1 drops as well.
When this occurs the 723 increases the voltage from pin 10 driving the pass transistors harder through Q1.
The more base current through the pass transistors, the higher the output voltage.

Thus we have regulation, the 723 continuously changing its output voltage to meet the minute changes in load on the
supply. Remember, the 723 does the thinking, the pass transistors do the work!

THE PASSING LANE
Let's look a bit at what the pass transistors do. The key thing here is current carrying capacity and heat dissipation.
In our example, lets say your power supply uses the common 2N3055 NPN power transistor.

This transistor can pass up to 15 amps of collector current. Note that it is not wise to
run any device at its maximum rating. Thus for a 25 amp power supply you would want to have more than
two 2N3055's in parallel. For the last supply I built, I used four.

If you used higher current rated transistors, you could get by with less of them.
If you simply placed the multiple pass transistors in parallel,
slight differences in gain between them would cause unbalanced current flow.

The highest gain transistors would hog most of the current flow and most likely fail.
To balance the current small value resistors called "Emitter Ballast Resistors" are
added in series with the emitter lead of each transistor.
These can be between .01 to .1 ohms and should be of at least a five watt dissipation.

Tolerances.

Try removing a turn from the coil (if it is one you wound) and/or adding
some capacitance.

You've probably got more parasitic capacitance in the circuit than that
10 pF represents. That means your capacitance range is more like 41-50
pF (figure picked out of the air) than 1-10 pF. Did the article suggest
any special construction techniques to minimize this?

I've been tinkering with an add-on project for a RS DX-394 receiver based on Stirling Olberg's (W1SNN) "Reciprocating Detector" design(s) published in Ham Radio in 1972 to 1978. Has anybody had any experience with this design. Is it fundamentally any different from a synchronous detector such as the NE602 design by OH2GF in the current ARRL Handbook?

Your prices seem to be current. I use some of the items you list.
Still I buy mine from those that I know have recent products...fresh supply.
You might lower your prices and sell more. Like the 7812 5/$4 7805 10/$5
These should be cheaper for surplus stuff.

There are several ways to combine the dds and pll.
If you do it this way, by using the dds as the divider in a pll circuit
your dds must accept the clock rate of the pll output frequency. DDS
circuits that operate at clock rates as high as 400mhz are now common.
The software to calculate the divisor constant for the dds given the
desired pll output frequency might involve floating point math, I briefly
looked at it and didn't see a clear way to do it with integers using an
8051.

Another circuit uses the dds to provide the reference (R) for the phase
comparater of the PLL and setting the output frequency is now a matter of
selecting the PLL divisor ratio and the reference frequency. The DDS
provides
the fine tuning, and the PLL the course adjustment. I worked up a
design where
the reference for the PLL was nominally around 100khz (actually 64 or 128khz
so it would be an even power of two). Then the software was an integer math
problem, though it did require either integer multiplication or
division. I was
able to invert the problem so only integer multiplication was required, and
a table driven routine will work fine on the 8051. In fact, I was able

to insert the
IF offset into the tables, and all the routines are in binary, NOT BCD.
A binary
to bcd conversion is required to display the frequency, and bcd to binary is
needed for keypad entry, but the rotary shaft encoder could drive in binary.

If anyone has build a radio using a dds/pll vfo, I'd like to know how
they handled
the user interface in software, which micros they used and how they
handled the
math to calculate the divisor constants.

I've read those articles, and specifically reread them last year, and
for the life of me I really not sure how it's supposed to work. The way
he explains it, it sure seems like there is some specific little bit that
is happening in there. If I'm remembering, he claims it works for FM
too, and I don't see how it could demodulate FM if it was just a synchronous
detector.

He references some professional article or paper as the source of
scheme, and one would hope if someone could get ahold of that, what
is going on might be clearer.

When I did some searches on the internet last year, I sure didn't find
anything more about it. A handful of Usenet posts, none of which added
to the scheme or even an understanding of it.

Fred, two recent news items:

1. A guy went into a liquor store to hold it up. After the proprietor gave him all the money in the cash register, the guy wanted a bottle of liquor off the shelf. The proprietor told him: "You look too young. I need some ID."

The guy pulled out his driver license and showed him he was of age.

Guess who was waiting for him at his house when he arrived?!

2. A guy ripped off some clothes items in a department store by cutting off the anti-theft sensors. He didn't know what the hell to do with them so he stuffed them in his pocket.

Store security nabbed his ass when he walked out the door!

Source record: 34280

I was wondering if anyone has an info about converting an AM radio to a SW one without down converting the signal? I have a defunct old valve superheterodyne SW reciever and an old transister AM/FM superheterodyne. Is it possible to replace the AM radio's tuning variable capacitors with the SW ones and get SW, or is it more involved than that? Any info will be greatly apppreciated.

I got started on this from a schematic sent to me by a Czech ham/swl who
also has a DX-394. He derived his schematic from a translation of one or
more of the articles. I'm not sure he understands it because he can't
explain well in English and my is Czech non-existent.

The design uses discrete transistors, not many parts and is cheap. I have a
breadboard version working, after a fashion. It does lock when within 200 Hz
or so and sounds pretty good. I was initially puzzled by an apparent null or
minimum audio in the centre of lock on DSB signals. It is fundamentally a
product detector with a synchronised BFO, so the difference products of the
two sidebands are anti-phase. I would assume that all synchronous demods use
product detectors and would behave similarly in that regard. It definitely
does better than the DX-394's envelope detector on DSB with selective fading
and fades out very gracefully and cleanly on weak signals, although lock may
be lost before signal is completely unreadable. At the moment my LO is very
unstable with temperature.

> He references some professional article or paper as the source of
> scheme, and one would hope if someone could get ahold of that, what
> is going on might be clearer.

I found most of Olberg's HR articles at the Metro Toronto Reference Library but did not look for the IEEE Comm paper by Badessa, who I think was a colleague. I don't know if synchronous detectors were in vogue in 1971 and were known as such. Did Badessa and Olberg coin the name "Reciprocating Detector" because it was truly pioneeering work uninfluenced by the name that eventually dominated or were they trying to get a patent by tinkering with the fundamentals and giving it a different name. The only obvious thing I can see that may be different is the 500 hz filter between the local oscillator and the product detector (that's the part I haven't got working yet - a straight wire is the minimum requirement).

> When I did some searches on the internet last year, I sure didn't find
> anything more about it. A handful of Usenet posts, none of which added

Hence my posting. HR accepted 4 or 5 articles on the RD or receivers using the RD by Olberg and there appears to have been considerable response. I daresay that, if this Usenet group had been around then, there would have been some hot and heavy debates about the Reciprocating Detector!

>involved than that?

It's much, much easier to build a converter for the band you want. But if you
are really ambitious....

Ok, it's not THAT hard, provided you don't plan on tuning a wide bandwidth.
First you need to replace the original RF tuning section with a new front-end, a
bandpass filter with steep slopes that covers the band you want to tune. Toss
the RF coil and disconnect the appropriate section on the tuning capacitor, both
of which will not be needed anymore. Then you must add a padder cap in series
with the local oscillator section of the tuning cap; and depending on how high
in frequency you want to go, you will need to either remove turns from the
oscillator coil or replace it completely. That's the fundamentals, but as always
there is going to be some fine tuning involved, like changing the values of
bypass or coupling caps, or modifying the wiring of the local oscillator to
handle the higher frequencies. Oh, and don't expect spectacular performance.

It's much more involved if you want to keep that tuned RF front-end. First you
need to determine what kind of tuning capacitor you have -- if it is designed
for AM BC superhet (one section smaller than the other) then you need to replace
it with one where both sections are the same. Then you will need to add some
padder caps in both series and parallel with the local oscillator section, and
modify or replace both the RF and local oscillator coils. All the values need to
be calculated depending upon what band you wish to tune -- a job not for the
timid as it takes numerous iterations to match the curves so the RF section will
track with the local oscillator to get a constant IF. Assuming you manage to get
all that done, you then need to align the padder caps so the two sections track.

BTW, I wouldn't even TRY this with the transistor radio, but with the tube radio
it might make an interesting project. You might also consider building a new
tuner (RF section, local oscillator and mixer) on a seperate chassis, then send
the output to the IF and AF sections of the original radio. That's how I did a
couple projects. Modification to the original radio involved only the addition
of a switch and a phono jack to the input of the 1st IF section. Just flip the
switch and the radio still works as before.

Source record: 34288

I have a Reciprocating Detector that I built from a kit of parts that I purchased from W1SNN back in 1972. I use it at 455kHz in an AM broadcast receiver to eliminate selective fading.

The IEEE Comm paper by Badessa lists the patent on the RD that you can look up. Also if you get a null in the center of the lock range you may be locking 90 degrees out of phase with the carrier.

It ain't worth it. You wouldn't replace the tuning capacitor, anyway. You'd
replace the RF and oscillator coils.

>they handled
>the user interface in software, which micros they used and how they
>handled the
>math to calculate the divisor constants.

Heres the way I do a simple integer division ...

j = i / 0.66 ... that's what we want, both i & j are int's

The same as ..

j = i * (1 / 0.66)

The same as ..

j = i * 1.5151

Have the 1.5151 as a look up in rom but scaled up by *256 (388 in int terms)

So you have ..

j = i * 388

Then you divide the result by 256 (a simple shift right by 8 bits)

eg ..

i = 54
i = i * 388
j = i asr 8 .... this gets rid of the scale up

or

j = i shr 8 .... for unsigned calcs

..

j now equals 82 (as near as you can get to 81.84375)

If the divisor is variable then you prolly have no choice but to do a proper
division at some point, but still use scaled up int's to get your result.

Clive

280. pin diode attenuators and switches

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-13 10:27:33 UTC
From: Active8 <mcolasono@earthlink.net>
Message-ID: <MPG.197afe11435dc8779896b1@news.earthlink.net>
Source record: 34296

Hi:

i've found out from my reading that pin diodes are only used as attns and switches down to about 10MHz. i'm wondering if i can use another type of diode as an attn or switch at lower freqs. i don't recall ever hearing that.

i think i've seen common diodes (maybe gen purpose signal diodes) as RF switches and the passive DBM can be used as an attn, though i'm not sure about the freq range for the DBM attn.

BTW i've got the HP app notes on pin diodes, but there's no info there pertaining to my question.

out of all the circuits i've seen, i'm beginning to think i'm stuck with things like dual gate MOSFETs for attnuation. or bipolars driven into the non-linear region. maybe JFETs or MOSFETS as analog switches.

i'll need to go down to 3MHz for now, but i'm interested in going lower and what the practical solution is for different freq ranges.

any suggestions would be greatly appreciated.

thanks
mike c

Where'd you get that idea? Back in 1975 I was using PIN diode T/R
switching and a bridged T PIN diode voltage variable attenuator in a
military HF transceiver (100W TX 2-30 MHx frequency coverage).

Both the T/R switching and the RX attenuator (in front of the 1st mixer
at RF) worked fine. In fact, the RX would take 2 tones 3 kHz apart
at 300,000 uV each and the 3rd order IM products were down 55dB
or better.

The key to using PIN diodes at HF is to select PIN diodes with a long
(say 2usec) "minority carrier lifetime" (necessary to minimize distortion
on lower freq signals. At the time "Unitrode" made the diodes I was
using ... but they may have been acquired by someone else, I can't
recall for sure because I haven't been in the market for such diodes
for some time.

>i'm wondering if i can use another

> about the freq range for the DBM attn.

PIN diodes are the best for RF switching ... other diodes will switch, but
don't have the same distortion characteristics.

BTW .. the common 1N4007 rectifier diode has a PIN structure and
has been used by many with some success in switching HF signals, but
I don't know offhand what maximum RF power level that particular
part will handle. (though I suspect it should be fairly respectable, since
the part is rated as a 1 Amp rectifier, IIRC.) Also note that AFAIK,
the 1N4007 is the ONLY part in the 1N400x series that has a PIN
structure.
>
> BTW i've got the HP app notes on pin diodes, but there's no info there
> pertaining to my question.

HP makes some very nice parts for lower powers and also for higher frequency use, but I'm not sure that they make a part that's capable of handling something like 100W of RF at 2-30 MHz.

One thing to keep in mind ... the more switching (forward bias) current used to make the PIN diode conduct, and the higher the reverse voltage used to reverse bias it to turn it off HARD, the lower the distortion created (within the current and reverse voltage ratings of the diode, of course).

IIRC, in 1975 I was using something like 10mA of forward bias for the diodes in the RX leg and about 500mA for the diodes in the TX leg of the T/R switch and the reverse bias was the full supply voltage of 12 or 28 volts, depending on which primary voltage the particular model of the radio was intended for ...

I hope this information is of some help.

Dear all
I have seen posts in the past about this issue
My friend has acquired a unit with the output stage defunct.
Any ideas about what the problem is likely to be and the solution?

Thanks
Richard

283. HF SSB Backpack portable

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-13 14:16:10 UTC
From: Richard Hosking <richardh@iinet.net.au>
Message-ID: <3f1169d7$0$23584$5a62ac22@freenews.iinet.net.au>
Source record: 34201

I am interested in acquiring a unit (or building a kit if such is available)
for backpacking with the following specs

Output around 5W SSB/CW
Tunable
Digital readout freq
All (or most) amateur HF bands
Light <1-2kg
Battery drain low on Rx (?< 100mA)
Rugged

Does such a unit exist at reasonable cost or is this the realm of military
style radios?
I would appreciate any pointers

Thanks
Richard

I use 1N4007 (PIN) AGC diodes in a 1.8 to 29.7 MHz
homebrew ham-band receiver at IF frequencies of
8.5 MHz and 3.4 MHz. They are in shunt with an
impedance level of 50 ohms.

PIN diodes have an intermodulation problem when
the forward bias is right at the threshold of
conduction. Ordinary diodes are much worse. At
higher/lower forward bias levels this effect
quickly goes away.

In order to assure that the 20 dBm third-order
intercept point of the receiver is not degraded by
this effect at the critical diode bias point, I
use three 1N4007s in series at each of the three
locations (verified by measurement).

A picture of this receiver is at QRZ.COM (W0IYH)

>ow hard would it be to wire up a third-party mic to an htx-252?

>tia!

Uses the common condenser mic / 2k to ground ptt circuit.
I use mine as a NCS station and wanted to use a headset so I
drilled a hole in the rear of the mic in installed a 3/32'' jack.
this allows me to use the regular mic and when I want to use my headset i just
plug the headset into the mic and the plug for the earphone into the extspk
jack(optional). I use the RS headset 19-312
which can be had at RS on closeout for $10.00. These headset are nice because
the plugs aren't siamesed and fit many different handhelds and do vox also.The
ptt is mounted on my clipboard so I can key with my left hand and log with my
right (sitting in my easyboy).I get many comments on the great quality of my
audio.
I have a link to the schematic for the htx-252 available on request.

>
> Any body use the 2955? Comments???

I've been using one here for nearly a year. They're good, solid,
basic units. Don't expect spectrum analyzer or tracking generator
functions (get an HP 8920B for that), but I've been pleased with mine.

Fair warning: Yes, IFR will support them, but they want $500 for
the service manual if you're self-maintained.

There are several that are fairly close to your specs.

The Elecraft K2 is a kit, does all you ask except the battery drain is about 120mA on receive as I recall. It can include a nice built-in wide range antenna tuner. It's not physically as rugged as some of the others but it should be fine as long as you don't throw it around unprotected.

The Elecraft K1 is a kit, does 4-bands, includes an antenna tuner, exceeds your current requirements but it is CW only. It's very well suited for back packing if you are willing to give up SSB. Makes a nice small package when the internal battery option is included.

The SGC SG-2020 is quite rugged but draws about 500 mA on receive.

Another possibility is the FT-817.

Generally, the MAR-x series is being replaced by the GALI-x series parts... Both by Mimicircuits, but the GALI parts are in a different physical package.

MAR-x parts are sill being made, but you may have better luck looking for the GALI-x.
The GALI parts usually go to higher frequencies. They also have better heat transfer from the internal junctions to the external ground so they run a little cooler and have more reliability.

MAR-x parts are sill being made, but you may have better luck looking for the GALI-x.

Sissy! :-)

The trick is to make the oscillator run at essentially the same power level whether it is oscillating or not. This means class A operation and you key the feedback loop instead of the oscillator itself. That way the tube or transistor has the same dissipation at all times.

It's a bunch of work to design and probably not worth it, but it *can* be done. (Just kidding about the sissy part).

as i said, from my reading (i'll let the author know when i come across
the article again). i know better than to believe everything i read.
that's why i'm getting a second (or better) opinion.

> Back in 1975 I was using PIN diode T/R

that would have been my guess from what i read in the HP app note #922.
that note was dealing with a diode where Fc was 10MHz, below which, it
acted as a regular diode. elsewhere they give Fc=1/2pi*t and mention
that t typically ranges from 3uS to .005uS so 3uS corresponds to
something like 35kHz. O'Tay, that's range i can easily live with. once
i've found some good specs i can do a cost/performance study.

i've noticed they're used for something other than rectifiers. i think
i've seen some of the ones like 1N4148 used also, thought i know not of
their structure. i'll keep my eyes open. i think they were used as
varactors, though.

just like the DBMs ring diodes need an LO drive that switches them fully
on and off. they (Mini-Circuits) even say a pulse (which i take also
includes a square wave) used for the LO drive can lower distortion.

you mean by doing that, the chances of all the diodes switching at the threshold is reduced?

The diodes are pretty much uniform, as compared to
many years ago. The reason for three diodes in
series is to divide the RF/IF signal voltage into
three approximately equal segments. This greatly
reduces the intermodulation in each diode,
therefore in the set of three. I verified this
with a spectrum analyzer plus tracking generator
equipment. Also verified many (33) years ago.

Bob, thanks forcoming back. I'm delighted to connect with someone who has a RD.

Do you not get null or minimal audio at zero beat in the centre of the passband with your authentic RD? I thought that this would be the normal response of a product detector on symmetrical sidebands - the negative frequency product would be antiphase of the positive frequency product. There is no such null on a SSB with carrier signal such as CHU.

What lock range do you get? Without the 455kHz filter in the feedback loop, I get about 400Hz. With a ceramic resonator of unknown interelectrode capacitance, I have been trying different values of parallel inductors and getting lock range of 100 Hz or less.

Do you find that the RD suppresses impulse noise and static crashes?

Hi Tom,

I haven't built any of the detectors but read some on them awhile ago.
I believe that if you get a null that the lock up is happening at 90
degrees out of phase. That cancels the audio. I remember reading
something about that in one of the articles and that there was a way
to adjust it but the rest is foggy.

There is an article on the Costa system in the old CQ SSB handbook.

Well let's see, the size of the supply has nothing to do with the
problem I am experiencing!

The reason I am using an Astron 50 is because it also runs the HF rig,
and all the otehr 13.8 volt equipment in the shact with much reserve
current.

When I bought the supply (New) from AES to go with a brand new
TS-450S, I figured you only want to di this once, so I bought all I
thought I'd ever need.

Try Whitesides on SR9 in the Clearview area for scrap steel and
aluminum. Lots of steel angle, etc. A few other metal and plastic
material scraps.

Vetco is now E. of where it used to be by maybe 3/4 of a mile or
so...if you go to Fred Meyer there, you will be VERY close; it's in
the FM complex, I think it's on the W. side. I guess Active is still
there next to where Vetco used to be.

I'm trying to talk myself into downsizing some, and might be able to
fix you up with some interesting things, depending on just what it is
you want to play with. There's also the possibility of loans of
equipment sometimes. I live nearby...

Cheers,
Tom

>
> Goddam newbies. :)

Now if you'd mentioned copper oxide, I might have been mildly
impressed... ;-) Seems like there were some iron based ones, too.
And then there's the coherer...

Not all early detectors were insensitive, however. Have a look at the
Marconi detector which uses a moving magnetic band. Seems like we had
a thread here about it a few years ago, and there was a nice article
about it in EW+WW.

All the seleniums I ever used ('cept for the shorted ones) worked a
whole lot better than 10001:10000!

Cheers,
Tom

308. Homebrew in Mpls/St Paul

I am JUST starting to get interested in homebrewing things, and I don't know where to start! I have reasonable good solder skills, etc, have done some minor projects, rig interface kit, electronic kits in HS, some cables etc... But I'd like to do more, like build a regenerative, eventually a little transceiver, all the while learning what to do with tubes, transistors and all the rest.

What I'd like to find is an Elmer in the Mpls area who would be willing to show me some of the stuff they've built, let me know where they procure their parts, maybe let me raid their junk box every once in a while.

Feel free to reply off the list, or on if you have information about the homebrew scene in Mpls/St Paul of interest to everyone else.

They tend to get fried by reverse power application. Best solution
would be to replace it with a part from a donor unit. Next bet thing
would probably be a 50-ohm MMIC like a GALI-5 that's capable of similar
gain and output power. I don't remember if the 8640B's output-power
sampler is built into its output stage, though; if it is, then some
careful hacking might be necessary.

Those Motorola FM transmitter ICs aren't particularly useful. By the
time you add the needed external components, you aren't really saving much.
And, for most amateur applications, you'll need some sort of multiplier
to get up to frequency, and most will want an amplifier. You might as
well start with discrete components, because you can get them easily,
you will get the design you want, and you would be saving very little
space with the IC.

The transmitter ICs are designed for 49MHz operation, yet the cordless phones
I've taken apart don't use them, and the 49MHz FM walkie talkies that I've
looked at don't use them. Instead, they use discrete components.

Doug DeMaw did write about the MC2831 in the March 1990 issue of QST,
though it was more an idea article. Looking in old Motorola databooks
will also turn up information about the ICs.

The receiver ICs are more useful, because they fit in more. Motorola
had a few generations of such ICs, starting with one that took 10.7MHz
and converted down to 455KHz and you'd get the audio out the other end.
There were various part numbers, again look in old Motorola databooks.
You do see these quite frquently in older cordless phones. Buying
such phones at garage sales has the advantage that you get the 10.7MHz
and 455KHz filters and the crystal to convert from the first IF to the
second. (Note, some of those phones use these ICs in a single conversion
configuration, going from 49MHz down to 455KHz directly.) If you're careful,
you could just extract the whole circuit from the phone (and indeed, you
get two such circuits, one in the base and one in the remote).

I found similar ICs in Radio Shack 49MHz superhet walkie talkies. I've
yet to check baby monitors to see if they use the ICs (or indeed
if they are even superhet receivers). These are pretty useful because
the boards are small, and either a bit of conversion of the front
end will put it on a useful frequency, or strip off the front end
and add your own.

Older cellphones, the bulky kind, will offer up lot so useful parts
including some sort of IF strip. I don't think I've found a recognizable
IF strip IC number yet. And they too will include the filters and conversion
oscillator.

Of course, at this point I've pulled in a number of FM two-way receiver
boards that have such things, or could even be used without conversion.

I've found these at the local hamfest, and they were going for a couple
of dollars each.

Motorola came out with a second generation of FM receiver ICs, that
were double conversion receivers in a package. So you wouldn't need
an external front end in front of the IC. I haven't seen these in
consumer equipment, and I'm not sure how available they were as
parts.

They even came out with a third generation of receiver ICs, not really
adding much in ways of features or integration, but did have higher frequency
performance. There were an article or two in the old COmmunications Quarterly
magazine.

Look in older books or magazines. Thirty years ago, such FM transmitters
were common in the ham literature. There isn't much sense in using
ICs for such transmitters, and synthesizers hadn't come into play,
so the transmitters were nothing but a crystal oscillator followed
by multipliers. Of course, for compactness you'd want to find something
that started with a relatively high frequency oscillator, say 48MHz,
so you wouldn't need all the multipliers.

There is bound to be something in the ARRL handbooks from that period,
at the very least.

Olberg's original article, in Ham Radio for March 1972, doesn't really
explain what is happening. I know I have the full set of his articles,
but the only other one I could put my hands on relatively easily was
the WWV receiver one, in Ham Radio for November 1972. It doesn't really
add to the explanation. He described a whole VHF receiver using the
detector, from an online index I think that must be the March 1973
issue of Ham Radio; I thought he made the claim that the detector worked
on FM in that article, but that might be a false memory. And he had
at least another one, in Ham Radio for October 1978; that one must be
the one where he uses an IC, and he seemed to go into great detail of
what the specific transistors in the IC did, but not much about the
overall picture. By way of explanation, I think he even shows a BFO
somewhere, which memory tells me was misleading. Maybe a bit more
digging and I can find the other two articles.

>
You do realize there is no oscillator in the reciprocating detector? That's
the odd part, at least in terms of SSB and CW.

Synchronous detectors had been around for quite a time, though I'm not sure
exactly when they came into play. Obviously, when tubes were all that was
available, it was too bulky to be common. Webb described a phasing type
synchronous detector in the June 1957 issue of CQ. The more traditional
type of synchronous detector (ie just an extra product detector added
to a PLL) had to be around before that, but Ralph Burhans had an article

about such an adaptor in QST in 1964. By the time of Olberg's first article, they were pretty common in the magazines, because ICs had made the simple synchronous detectors really available. By or around 1972, Ham Radio had a number of articles about synchronous detectors, using various schemes.

There was even an article in the mid-fifties in QST about a two IF chain receiver. One was voice-bandwidth, the other CW bandwidth. But the real trick was that one could feed the narrow IF output into a the bfo input of the product detector at the output of the "wide" IF, and use it to beat against the incoming signal. A form of a synchronous detector.

You can lock to a carrier, just filter and amplify the weak carrier or extract the beat between two sidebands, and all will generate a "carrier" where it's needed. But with an SSB signal, you don't know where to place the carrier.

What doesn't make sense (or which makes the reciprocating detector different from all these) is that there is no BFO. You could imagine that it's just a variation on some of these previous schemes, ie regenerating a carrier, except that it claims to work on SSB (and CW for that matter). Yes, it's filtering something from the incoming signal, but in the case of SSB and CW what is it extracting to beat against the incoming signal? The only real hint at something is that the filter is at the output of the switched differential amplifier.

There is some hope, and after all these years I can add a bit to the documentation. No, I don't have the IEEE Conference. But going to the US Patent Office website at http://patft.uspto.gov and entering Badessa's name, I did find a later patent that referenced one of his. So either US Patent #3,430,151, "Amplitude modulation detector for single sideband or suppressed carrier input" filed in September 1966 and issued in February 1969 is an earlier development, or is indeed the patent for the "reciprocating detector".

I can only see a bit of the page at a time, so I haven't bothered reading it yet, but maybe that patent has some of the answers. Certainly when I did some searching last year, nobody had bothered connecting a patent number to the scheme.

I didn't see much response. The whole thing seemed to be propelled by Stirling Olberg, and I never saw anyone else use the circuit in

a ham magazine article. Indeed, other than any followup letters, there were no references to his articles. And nobody really seems to know what's going on in the circuit.

Regarding MiniCircuits Vs HP and so on, the same chips are used by several manufacturers in their own packages so you will see virtually the identical part appear to be made by a couple of companies.

In this case, the MAR series equivalent is made by at least three companies to my knowledge and MiniCircuits is one of them.

Hi Troy,

I recon someone else may have sent you this but

http://www2.arrl.org/tis/info/pdf/0009061.pdf

This is, I think, one of the best examples of a good beginners regen radio.
Most of the parts except the variable cap and the 1N34A can be had from
Radio Shack. You can go to

http://www.danssmallpartsandkits.net/

to get those parts and more.You might also try

http://www.midnightscience.com

They have a lot of good stuff on crystal radios.

Crystal radios are a good way to learn basic theory if you follow along with
the why for's of each stage.

> Digikey and Mouser don't seem to carry them. Any ideas?

If you aren't particular about brand or package, both Digikey and Mouser
sell NEC/CEL MMIC's. The Digikey parts are only in SOT-363 packages
(6 pin, 0.65 mm lead pitch) and Mouser has some in the older pill packages
(but they cost several times more than the more modern packages).

Both Digi-Key and Mouser have a good selection of NEC/CEL bipolar microwave
transistors.

I recently used some NEC uPC2712's from Digi-Key and was very satisfied
with the results. Digi-Key also has NEC GaAsFET's.

Tim.

321. help building oscillator

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-15 16:54:38 UTC
From: Jock Cooper <jockc@mail.com>
Message-ID: <m365m3wx0x.fsf@jcooper02.sagepub.com>
Source record: 34238

Hi everyone,

I've been interested in radios and how they work since I was a kid -- I had a crystal radio kit and a RF-2200. Recently I started building radios and have been having a blast. Please keep in mind that I am very newbie.

After scouring the web for am radio circuit schematics I found quite a few and successfully built several of them (I'm using breadboards). Then I wanted to get a little more sophisticated so I got some NE602s and started to work on a superhet ish type design -- basically cobbling together bits from other circuits. I had some decent success using the NE602 internal oscillator (although getting the oscillator to track the rf input is tricky), then I wanted to use an external oscillator.

I tried numerous circuits and numerous types (Hartley, Colpitts etc) I had found but I couldn't get any of them to start up. Finally somehow I got one working reliably: it was a JFET Clapp with a JFET buffer amp. I hooked up my Elenco LCR to it to measure the frequency. I was using a 3 gang 10-500pf air cap and a coil I wound onto a pill bottle. The oscillator was running from 980 khz to 2050 or so. I fed it into the NE602 pin 6. Only problem was (again) I had a hard time getting the main tuning (also on the 3 gang cap) to track the same range (well the same minus 455). I guess I had plenty of stray capacitance or something that was mucking up my calculations. So at say 540 they would line up but tuning to the other end they'd be off by a few 100 (!) khz.

So I decided to build a second oscillator to help align the antenna tuning tank. I pulled out one of those little 'mini' breadboards and basically dupicated the working oscillator circuit on it. Only this time no startup. I also moved it to a second breadboard but still no good.

Now I'm at a loss as to how to proceed. How do you diagnose a bad oscillator circuit? I thought about measuring the voltages all various points on the working osc while it was running and comparing those, not sure how much that will tell me.

Also, a related question. I tried winding a toroid with the same inductance as my pill bottle coil, and hooking it in place of the pill bottle coil in the working oscillator. But it wouldn't start then. Any clue why this might be the case?? Also I have seen some circuits that call for a 1mH RF choke.. Can I wind a toroid for this? I don't have any chokes that high.

thanks for any help and apologies for any dumb questions,
Jock Cooper

I don't know of any good way to troubleshoot an oscillator without an oscilloscope and signal generator, except to measure all the voltages. However, the voltages can be right and the oscillator still not oscillate. Or you can find that some voltages are different simply because it's not oscillating. Perhaps someone else has some tips that can help.

Your problems with oscillators are possibly caused by poor component choices. Capacitors should be low loss types, like mica, NPO ceramic, or polystyrene plastic, and should be physically small so they don't have much inductance. NPO ceramic has the lowest temperature coefficient so is the best choice for stability. If you have a poorly made inductor, the temperature drift of a polystyrene capacitor might more-or-less cancel it, but that's a poor way to get stability.

Inductors also have to be low loss, and that's probably the answer to your question about the toroid. There are just one or two types of ferrite that might be usable for an oscillator inductor, but they're uncommon so you're unlikely to have them in your junk box. All other kinds of ferrite cores are too lossy for this use. You should use only powdered iron cores. In my experience, the best is type 6, which is colored yellow and typically with a glossy finish. Type 7, colored white, should be similar, although it's much less common. I wouldn't use any other type of toroid core except these two types of powdered iron.

Ferrite is a good core choice for the RF choke, although you might have trouble with core saturation if you're putting a fair amount of current through it. Chances are you don't really need a choke with a value this high, although you might in some applications.

Don't apologize for the questions! We all had to start somewhere, and are glad to see you learning. And you never learn much from circuits that work -- it's the ones that don't which are educational.

I have bound volumes of HR going only to 1973 and did look up the '74
article to refresh my memory.

Stirling's description isn't quite good enough in the '74 article covering
the included "reciprocating detector." The principle is that of simply
filtering out the carrier, amplifying it, and mixing it back with the
incoming carrier-plus-sidebands. At the output the carrier, mixed with
itself, becomes a DC level. The sidebands mix with the amplified-and-
limited/filtered carrier to result in the original audio.

Motorola used the same principle in the MC1330P video detector chip
introduced in the early 1970s (1972?). The 1330 had what amounted to
a limiter ahead of the mixing stage. The so-called "capture effect" of
the limiter will output the stronger signal which, in this case, is the AM
carrier. For the "filtering" (as Olberg called it), the 1330 used a simple
resonant circuit tuned to the carrier frequency.

Analog TV, both in North America and elsewhere, sends video sidebands
as mostly one of them with just part of the other sideband, and with the
carrier reduced to roughly half of what it would normally be with AM.
[so-called "vestigal sideband" with just a vestige of the lower one in US
NTSC standards] The resultant reduced carrier level is still good enough

to grab, limit-filter, and reapply in a mixer to recover just the video of the
TV sideband. In the MC1330 application with TV carriers in the 50 MHz range, balanced internal mixing and assorted internal capacitances allow about 6 to 8 MHz video bandwidth detected with hardly any of the carrier leaking through. Slight lowpass filtering can get rid of the carrier.

Olberg claimed that (in the '74 article) the "reciprocating detector" did not handle overloads well. While I've not examined that in detail, nor did I read HR in that year, I used the MC1330P in 8 simultaneous RF pulse detectors in an airborne receiver for an R&D project at RCA. Those RF pulses were all 1 uSec wide at different RF carriers between 55 and 64 MHz and there was very little pulse distortion at the output of any one detector without its input SAW filter. In the RF environment the RF pulses would have up to 30 db variation in peak envelope power. The MC1330 detector circuit wound up as a rather linear detector of RF input amplitude versus video output amplitude over that 30 db range. I was quite pleased with the results considering an impossibly small space allowed for 8 detectors (non-optimized hand layout PCB was about 1" x 1 3/4" for each detector). :-)

Offhand, after a long and thoughtful 20 minutes after reading Olberg's '74 HR article, a narrowband (IF) filter could pass the carrier through to any FM-style limiter IC, its output to a balanced mixer (differential, double-balanced bipolar or FET) which could then output just the side-band content of an AM unsuppressed-carrier signal. If the limiter gain was high (that is, limiting threshold low), front end noise would get through and appear at the demodulated output...but that noise band-width would be only as high as the narrowband IF filter bandwidth. Once a carrier was there, it would take over in the limiter and demodulation would become essentially linear. Impulse noise received could be reduced depending on the relative peak IF power of noise pulse versus carrier...the limiter stage would take over and pass the higher input level while suppressing the lower input level.

I doubt that this "reciprocating detector" would be good for any FM except quite narrowband FM...due to the bandwidth of the filter. That was another claim by Stirling Olberg in the 1974 article. FM carrier level would vary with modulation (although entire carrier plus sidebands would remain constant) and that would mess up the carrier reinsertion part of the "RD." Might be okay for PM. Have to do the numbers to see if that is feasible and my 20 minutes was up. :-)

All in all, interesting stuff to see and consider!

I have bound volumes of HR going only to 1973 and did look up the '74
article to refresh my memory.

Stirling's description isn't quite good enough in the '74 article covering
the included "reciprocating detector." The principle is that of simply
filtering out the carrier, amplifying it, and mixing it back with the
incoming carrier-plus-sidebands. At the output the carrier, mixed with
itself, becomes a DC level. The sidebands mix with the amplified-and-
limited/filtered carrier to result in the original audio.

Motorola used the same principle in the MC1330P video detector chip
introduced in the early 1970s (1972?). The 1330 had what amounted to
a limiter ahead of the mixing stage. The so-called "capture effect" of
the limiter will output the stronger signal which, in this case, is the AM
carrier. For the "filtering" (as Olberg called it), the 1330 used a simple
resonant circuit tuned to the carrier frequency.

Analog TV, both in North America and elsewhere, sends video sidebands
as mostly one of them with just part of the other sideband, and with the
carrier reduced to roughly half of what it would normally be with AM.
[so-called "vestigal sideband" with just a vestige of the lower one in US
NTSC standards] The resultant reduced carrier level is still good enough

to grab, limit-filter, and reapply in a mixer to recover just the video of the
TV sideband. In the MC1330 application with TV carriers in the 50 MHz range, balanced internal mixing and assorted internal capacitances allow about 6 to 8 MHz video bandwidth detected with hardly any of the carrier leaking through. Slight lowpass filtering can get rid of the carrier.

Olberg claimed that (in the '74 article) the "reciprocating detector" did not handle overloads well. While I've not examined that in detail, nor did I read HR in that year, I used the MC1330P in 8 simultaneous RF pulse detectors in an airborne receiver for an R&D project at RCA. Those RF pulses were all 1 uSec wide at different RF carriers between 55 and 64 MHz and there was very little pulse distortion at the output of any one detector without its input SAW filter. In the RF environment the RF pulses would have up to 30 db variation in peak envelope power. The MC1330 detector circuit wound up as a rather linear detector of RF input amplitude versus video output amplitude over that 30 db range. I was quite pleased with the results considering an impossibly small space allowed for 8 detectors (non-optimized hand layout PCB was about 1" x 1 3/4" for each detector). :-)

Offhand, after a long and thoughtful 20 minutes after reading Olberg's '74 HR article, a narrowband (IF) filter could pass the carrier through to any FM-style limiter IC, its output to a balanced mixer (differential, double-balanced bipolar or FET) which could then output just the side-band content of an AM unsuppressed-carrier signal. If the limiter gain was high (that is, limiting threshold low), front end noise would get through and appear at the demodulated output...but that noise band-width would be only as high as the narrowband IF filter bandwidth. Once a carrier was there, it would take over in the limiter and demodulation would become essentially linear. Impulse noise received could be reduced depending on the relative peak IF power of noise pulse versus carrier...the limiter stage would take over and pass the higher input level while suppressing the lower input level.

I doubt that this "reciprocating detector" would be good for any FM except quite narrowband FM...due to the bandwidth of the filter. That was another claim by Stirling Olberg in the 1974 article. FM carrier level would vary with modulation (although entire carrier plus sidebands would remain constant) and that would mess up the carrier reinsertion part of the "RD." Might be okay for PM. Have to do the numbers to see if that is feasible and my 20 minutes was up. :-)

All in all, interesting stuff to see and consider!

Source record: 34244

I should also mention that your problem with oscillators could be related to layout techniques. There are some rather staggering currents circulating in the tank of a well designed oscillator. You don't want these straying to other circuits, encountering much loss, or the fields they create coupling to other circuits or lossy objects. So here are a few rules, most of them also applicable to RF circuits in general:

1. You don't impart magical properties on a group of connections by calling them "ground". If two "grounds" are separated by a current-carrying conductor, they'll be at different potentials. This can cause a whole lot of problems, so

2. Choose one physical point in your circuit (not necessarily a whole receiver, but say an oscillator) to be "ground". Connect all "grounded" components directly to that point. This includes, especially, bypass capacitors and, in the case of the oscillator, the bottom side of the inductor (if grounded) and the bulk of the tank capacitance. This might not always be possible or practical, but always strive for this. Then connect the invividual circuit ground points together, following the general route of the signal flow. (You'll come to learn that "ground" is just one of the two signal conductors.) For example, if the LO connects directly to the mixer, the LO ground should connect directly to the mixer ground.

3. I highly recommend "ugly" construction, where components are built over a solid ground plane. High value resistors can be used where necessary as physical supports where natural supports like bypass capacitors and other grounded components aren't available. If you use this construction method, you should still follow the single-point ground rule as closely as possible, but it becomes less critical than when "grounds" are connected by wires or PCB runs. There are variations on "ugly" construction, involving cutting pads or islands in the ground plane (not a good idea), or gluing little PCB pads on top of the ground plane (harmless unless the PCB pad dielectric becomes significant -- it makes a crappy capacitor). Each has its adherents -- zealots, even -- but in my opinion they just add a lot of unnecessary work. At best, they don't improve performance a bit, and at worst they can degrade it.

4. In an oscillator, connect the inductor and bulk of the tank capacitance directly together, then connect the combination to the remainder of the circuitry from their junction. For example, if the L and C are in parallel as they are in many oscillators, first connect the L and C directly in parallel, then connect one wire to the top junction and run it to the rest of the circuitry. The bottom junction is grounded in many oscillators. If it is, connect it to the single oscillator

ground point. The object here is to keep the large current which is sloshing back and forth between the L and C from traveling around and about. Give it a short, direct path to flow, and don't make it flow around, under, or through the rest of your circuit. In a ham-band VFO, the tuning capacitor is often only a fraction of the total tank capacitance, the rest being a fixed C. In that case, the larger amount of fixed C is most important.

There are a bunch of other factors to consider when building RF circuits, but following these rules will give you a good start, and a good chance of having things work like you intend them to.

Yup to everything that Roy said, and I'll add a couple comments of my own.
Depending on the type of breadboard that you're using, the capacitance
between the rows of contacts can upset RF tuning. At the relatively low

frequencies that you're using, that shouldn't be having that much of an effect,but you can't rule it out entirely.
I assume, that since you're trying to build a superhet radio, that you're tuning the oscillator and RF with a multi-section variable capacitor. I'll bet that you're using a variable with equal capacitance on each section.
Wrong!! Since the frequencies that the oscillator needs to tune is different from the RF tuning, then you need to select a variable with a high capacity section for the RF side, and a lower capacity section for tuning the oscillator. Take a look inside an old tube superhet radio and look at the tuning capacitor. Notice that one section has very large plates on the rotor and the other section has plates that are about 1/2 to 2/3 the size of the large (high capacity) section. That's probably why the oscillator isn't tracking the RF tuning.
Now, to get the oscillator to run reliably, you may need to separate the connections on the breadboard a little more. Instead of connecting somponents to adjacent rows, separate them by two rows. That will reduce the capacitance somewhat. Are you using a suggested circuit from the data sheet of the NE602? If so, be sure you use suggested types of components, especially capacitors. They can be notoriously problematic if they are the wrong type for the application.

A general coverage receiver is a good piece of test eqpt. Tune the rx to
the approx frequency of one that works to get a good idea of how to couple
and how loud it should be. CW or SSB is easier to use than AM. You can
also couple the LO of a receiver to use it as a test LO or signal gen.
good luck

> oscillator circuit?

Roy offered some good advice. No need for me to try to duplicate it!
But I know there can be a lot of times you just don't see something
that would be obvious to someone else who has more experience. If you
can find someone locally to have a look at things, the answers might
come a lot quicker. Failing that, if there's a place you could put up
some pictures on the web, that might help.

Are you using known-good circuits? Sounds like you probably are,
given that you understand the differences among the various types of
circuits. But it might be good to get your hands on a book with a
bunch of circuit ideas in it, if you don't already have one (or more).

Cheers,
Tom

334. NEED- Coil Forms

Hello-
I need a quantity of these coil forms : plastic, slug tuned, 20 - 200 Mhz. core. Form is simple plastic about .16 to .22 OD, about 1" tall, with tiny base flange. No terminals needed, the form simply pushes up thru tight fitting hole from bottom of PC board and is wound in place.These are the same coils as found in Microwave Modules transverters.Thanks, Byron WA5THJ.

335. Re: help building oscillator

Source record: 34102

I highly recommend _Experimental Methods in RF Design_, by Hayward, Campbell, and Larkin, available from the ARRL or your favorite book seller. All the circuits in the book have actually been built with the component values shown, and have been designed by people who know what they're doing. My personal favorite oscillator is the one shown in fig. 4.4 on p. 4.3. It's a dead-simple Hartley, is very stable, and just about bulletproof. I've made versions from 2 to over 100 MHz, and they always oscillate. The authors say in the book that they've made versions from 1 MHz to 3 GHz. You'll also find equations so you can calculate the capacitors you need for a given tuning range, and a wealth of other information.

Although it's a terrific bargain at the price, some people balk at spending the money for it. If you're one of those, check your local library. They might not have it yet -- if not, ask them to order it if they haven't already.

[tale of woe deleted]

I'd start again with a simple Hartley oscillator using a tapped toroid (you don't need a choke). Get the basic oscillator working (a scope helps) then add a buffer stage.

Forget about getting the oscillator and front end tuning to track properly at this stage, use separate capacitors. When you get the thing working properly you can sort out the tracking.

Message-ID: <3F14D6CE.2010401@hotmail.com>
Source record: 34106

I'm trying to make a simple Hartley VFO. I've made one before no problem, but this one won't start, period. The only difference between this one and the last one is that I used a T50-2 core instead of an air core inductor. Is that likely to kill it?

Also, last VFO I made, I tested it by feeding it and a signal generator into a product detector to listen for a tone, this one I'm trying to use a frequency counter to make things simpler. It reads crystal oscillators no problem, and I've even used it to read a VFO in another receiver, no problems.

Rich,

I'm glad you didn't say "dated info that's useless", which is how I
first read this. :)

I still have the 1993 edition sitting here, they do have some great
stuff in them.

What type of Hartley is it? If it's one with a separate coil for feedback,
you may have the phasing reversed. Just swap the connections on either the
mail tank coil or the feedback coil, but not both.

Hi Jock,
there is nothing you should apologize for. My recommendations:
1/ Do not use breadboards for RF. They are perfect for AF, good for digital citcuits, but RF circuits sometimes work, more often not. And keep the groundplane as big as possible. The "ugly", "rats-nest", "dead bug" or "manhattan" style really seem to be far the best for RF prototyping. Look at http://w1.859.telia.com/~u85920178/blocks/deadbug_0.htm for more info.
2/ Get an oscilloscope covering at least three times your frequency range. An add-on unit for your PC can turn it into an oscillscope and spectrum analyzer for a fair price.
3/ Use the necessary tuning capacitors and their configuration to keep the oscillator and input frequency near to each other at more than one point. The configuration and formulae can be found in many books.
4/ Try the oscillator from http://w1.859.telia.com/~u85920178/blocks/osc7m00.htm ,it should work reliably in a wide frequency band.

Most likely answer is that you have the phase of the feedback reversed
(negative instead of positive feedback). You should be getting better
coupling with the toroid core, so the optimum turns ration may be one
with fewer turns on the feedback winding, but this would show up as a
very distorted output, not lack of oscillation.

Hmmmm. Been a long time since I thought about the r-d.

IIRC #1: It (the reciprocating detector) would detect SSB and c-w, and it was silent between SSB bursts and c-w characters.

IIRC #2: It was best preceded by mode-suited, steeply-sloped filtering.

I recall speculating, back then, that its operating principle was to generate the bfo signal by ringing a bfo tank, offset from the incoming signal, with the bursts of incoming signal. When the tank ceased oscillating, the r-d output was silent.

A mode-suited, steeply-sloped filter ahead of the r-d would help keep its bfo tank from being rung by unwanted (off-frequency) signals.

The bfo offset required for these modes, and thus non-synchronousness of the bfo with the incoming signals, I think, might help to support, to some degree, the speculation above, as well as to explain the use of "reciprocating", rather than "synchronous", as part of the name.

Thinking about it now, I simply can't recall any attraction other than novelty ;o)

There are 2 approaches ... build a PIN diode switch (using PIN diodes
rated for the frequency and power levels involved and biasing them properly
to avoid unwanted non-linearities) or you could look into some of the GaAs
MIMIC switches made by NEC ... some of them can handle the power,
they typically switch in about 20 nsec, and they have the advantage of
requiring essentially no drive current (can be driven directly from 3-5V
CMOS outputs).

For data sheets, check California Eastern Labs' website at:

http://www.cel.com/prod/prod_rfics.asp

Scroll down to the GaAs section.

Look for a part with the highest 1 dB compression point available.
(for example a part with a 1 dB compression point of 33 dBm (2W)
would be more likely to generate undesirable distortion than a part
with a higher 1 dB compression point)

(CEL is the exclusive distributor in the US for NEC's parts)

>Can anyone reccomend a good small surface mount FM receiver chip that is currently availible?

I guess just use the current standard chips and do a triple conversion.

>Is it possible to do FM reception with a Direct conversion RX and some simple DSP?

Yup :)

You need the standard IQ signal from the mixer.
Just look for Demodulating FM using DSP (or something or other) on the net,
should come up with something.

I did find the info myself a few weeks ago but can't find the exact link atm.

Something like ...

```
R = (RxI * RxIprev) + (RxQ * RxQprev);
I = -(RxQ * RxIprev) + (RxI * RxQprev);
if (R = 0) then R = 0.0000001; // stop a divide by 0 error poping up
FMDemod = ArcTan(I / R) * SampleRate / (pi * 2);
RxIprev = RxI;
RxQprev = RxQ;
```

RxI & RxQ are incoming samples from a stereo ADC, SampleRate is the sampling
rate for the ADC.

Use the Cordic routine for use on a relatively slow cpu - inplace of the ArcTan.

I assume he is now a Silent Key - his call sign W1SNN is now
unassigned. Reading the preceding patent by Badessa, it seems more
complicated than what you describe but perhaps it boils down to that -
the complexity is in understanding the technique with which the
carrier is "synthesized" (his word). What you describe is a
"quasi-synchronous" detector; Badessa/Olberg talk about synthesizing a
carrier for suppressed carrier AM based on the carrier phase reversal
at zero crossings in the modulation envelope - the fundamental carrier
extraction also works on AM with carrier without the phase reversal
and it's my impression that the product detector itself oscillates at
the feedback loop filter frequency in the absence of a lockable
carrier.

The way my implementation behaves, I would say it has a synchronous
BFO. It sounds similar to a conventional BFO/product detector except
within the lock-in range, where it locks on to zero beat. I'm not sure
I have it functioning as Olberg intended or that Olberg's design is
consistent with Badessa's patent. The latter seems to claim phase
lock, except when there is a beat frequency. Both are silent about the
phenomenon I observe of an audio null on DSB AM carrier signals at a
certain point within the lock-in range. A couple have suggested that a
90 degree difference between carrier and reference would cause this -
(however,)it's not evident on SSB AM with carrier (e.g. CHU at
3330kHz). If so, then it would seem that the phase difference changes
across the lock-in range and passes through 90 degrees at one point
only. Wouldn't this be typical of all synchronous product detectors?

A hint that audio nulling may indeed have been a negative factor in
the RD is in Olberg's HR'78 article on the 10.7MHz RD where there is a
phasing network that does not appear in the earlier low frequency
models.

[snip]

I have been quite pleased with the dynamic range of my RD in
combination with the output levels from the 2nd last IF amp of my
DX-394. I do hear a strong click on the initial pulse of strong
carrier for CW Morse characters that I have not yet concluded is
related to the AGC action of older receivers to which attributed some
overload problems. My modified AGC should have an attack of between 2
and 10 ms and I have turned AGC off and still get the clicks, IIRC.

I have not compared my RD output to the envelope detector output under
controlled listening conditions. RD goes to my old stereo and Dynaco
A25 speakers; ED goes through the narrower bandwidth audio amplifier
of the DX-394 to a 4" speaker. When locked, RD sounds pretty clean!

> I doubt that this "reciprocating detector" would be good for any FM

>
For FM demodulation, he claims that converting the narrow-band crystal
filter that follows the feedback filter to an LC circuit makes a
frequency discriminator. In his Companion Receiver project, he
switches between the two filters for the two modes. My RD works with
the AM modes with/without the crystal filter (actually mine's ceramic)
and with an LC 455kHz resonator in parallel with the ceramic filter.
With straight wire, the lock-in range is on the order of 400Hz; with
the others, it can be reduced to less than the nominal 50Hz tuning
steps of the DX-394. I have yet to find a NBFM signal.

> All in all, interesting stuff to see and consider!
So far, it has been all of that and the parts cost is low.

You can convert directly down to I and Q baseband with two mixers and a
quadrature oscillator, then demodulate the baseband signals with a DSP.

> wrong type for the application.

Yes, I am using the ganged air capacitors; I have a few different
ones. I have a two section 15-390 each, a three section 10-500 each,
and a 5 section (something like three 10-30s, a 10-240 and a 10-90).
(these are from memory, I'm at work). So I've been experimenting with
differnent capacitance ranges and different inductor values and three
oscillator types: clapp, colpitts and hartley. I figured that the
oscillator's cap range should be smaller because it seemed that that
was how it was in most radios. But I also hoped that by working in
some extra capacitors in series or parallel with the larger ranged
variable capacitor I could get the tank to the proper range. In fact
I wrote a little software function (brute force algorithm) that given
a lo and hi Freq and Cvar would spit out values of cpar and cser which
would satisfy the equation

Flo = 1/ (2*pi* sqrt(L*Chi))
Fhi = 1/ (2*pi* sqrt(L*Clo))

Clo and Chi are derived by combining the actual cvarlo and cvarhi (eg 15 and 390) with test values for a parallel and serial capacitance.

the output is something like:

found: [[15-500 parallel 6] series 319] l= 444.8477/443.9821
found: [[15-500 series 320] parallel 6] l= 431.1616/431.9100

I wasn't sure if this was even OK to do (if it is too lossy or someting), I figured I could experiment around with the result and find out :) But maybe now I can just ask.. how much mucking around can I do by adding in parallel and serial caps to tweak the variable cap range? Also, Can I just find any old values of L and C that when plugged in would give me the F I'm looking for? Or are there only certain values of L and C that are appropriate for certain ranges of Freq.

A side note: In fact I *was* able to get my currently working oscillator to range 995 Khz - 2055 Khz with the 15-500p var cap and a parallel cap. The problem was the main tuner (also using 15-500p) wasn't tuning exactly 540 - 1600. Which is why I decided to build a second oscillator, so I could try to pin down the main tuning range, by tuning the oscillator to known values (using freq counter) I could figure out the range and how certain tweaks would affect it.

Thanks to everyone for the great and helpful suggestions. This sure is a friendly group.

Since I just recently started all this tinkering, my junkbox is a little low in some areas, notably NP0 capacitors.. I have a few in values from 3.9 up to 47 and a few 100s but not else. So I've used various other types when higher values are called for.. I'm planning on picking up an assortment soon.

Also I have some copper clad non drilled pc boards, I'm going to try to rebuild the oscillator (and radio) using the 'ugly' method; although I'm a little afraid I'll make myself a tangled mess of useless and stuck together parts. The main reason I use breadboards is so that I can take parts in and out of the circuit quickly (ie I'm at the stage where I'm curious about what happens when I take such and such part out, or change its value etc).

I'd love to get a oscilloscope but my 'play' budget is mostly spent for awhile. So I've been making due with an LCR and a little cheapo DMM.

I did order the book _Experimental Methods in RF Design_ .. I've also got a lot of good info from an old (well 1998) ARRL handbook I got on Ebay.

>
In the September 1972 issue of CQ, Irwin Math in his Math Notes column had
a circuit for a crystal controlled superregen receiver. The same column
had that then novel transmitter in an IC, the LP-2000.

It was simply a cross-coupled multivibrator made up of two transistors,
running at 20KHz, with a tank circuit with a crystal added in. He said
the one he built at 10MHz worked fine. He pulled the circuit out of
an issue of EDN, but no date is given.

Charles Kitchin had an article in the May 1997 issue of QST about a
crystal-controlled regen receiver (for receiving 80meter W1AW code practice
runs).

In the Q&A column in CQ for May 1960, there is a circuit for a crystal
controlled Q-Multiplier, which is basically a pierce oscillator. Apparently,
the circuit was originally in the RSGB Bulletin for February 1960.

In October 1961, there is a simple portable transceiver described in CQ,
and it too uses a crystal controlled regen detector.

Likely there are others, but those are the ones I know about.

Admittedly three of those four are regen and not superregen, but that's
hardly important since a superregen is just a regen detector which
is oscilalting and modulated with an above audible frequency. (And take
note that a Q-Multiplier is just a specific application of regeneration.)

Indeed, a regen is just an oscillator with controlled feedback, or
to look at it another way, a regen is just an amplifier with positive
feedback.

So you can take just about any oscillator circuit, and by adding some
sort of control so you can reduce things so it's on the verge of oscillation,
you've got a regen detector. Coupling into it may be easier with some
circuits than others. And once you've got a regen circuit, adding
some scheme to modulate it at an ultrasonic frequency will make it
a superregen.

Since a crystal controlled superregen is relatively rare (who knows
why), you might want to start things by going through this sequence

and figuring out the best setup yourself.

Someone once pointed out here that for a lot of uses you don't need ultra selectivity, and so a crystal in a regen is out of place. I'm not sure how this translates to a superregen.

Be advised that while there has been some work done on using better tuned circuits in a superregen, it seems more likely that the reason for it's passband is because it is in effect an oscillator that is being modulated. Working on the quench circuit, both amplitude and waveform, would seem to be a better path. Charles Kitchin has done some work on this, and he claims he has gotten better results by fiddling with this. I've never seen the article, but he wrote about superregens in the Fall 1994 issue of Communications Quarterly. His article about regens the following year was an interesting mix of history and new circuits, and I suspect the superregen article is similar. He's also had a few superregen circuits in QST (and in the Handbook for an issue or two), but I don't have a bibliography handy. There was a superregen receiver article of his on the ARRL site, http://www.arrl.org at one point, and doing a search there would hopefully find it.

Take note that most superregens use the same active element as both the RF oscillator and as the quench oscillator. Separating them, has certain advantages in trying to get the best quench, and these days it pretty much costs nothing to add the extra circuitry, unlike in the 30s when the superregen was pretty hot.

I'd be curious about why you think you need a crystal controlled superregen. Most superregens have been at VHF (indeed, if you go by some rules of thumb of making the quench frequency a certain percentage of the operating frequency the quench will be at audio once you get below a certain frequency), and getting a crystal to oscillate up there may start being a problem especially the higher you go. Though, I think some work has been done with SAW controlled superregens. And whether it adds to selectivity is under question. Stability might be a factor, but then the traditional wide bandwidth has always offset any issue of frequency stability. Who cares about drift when a superregen's bandwidth would basically cover most of the 2meter band?

I'm pretty sure it's just an amplifier. I took a very quick look at
the schematic this morning for my HP8640M, which should be the same.
I believe it's 18dB gain. As you say, it must be capable of the
output power. GALI-51 would be a bit closer match for the gain, but
not quite enough output power?

Cheers,
Tom

>
While the MC1330 internal schematic is not well layed out for clear
understanding, it is different from the reciprocal detector.

Unique to the RD design is the fact that the filter is at the output of
the differential amplifier, what it sees at it's input is not just
the incoming signal, but the incoming signal modified by the output
of the filter. That seems to be a key to the design.

The MC1330 splits the incoming signal, with one path going to a mixer,
and the other path going throught a limiter and filter which then feeds
the other input of the mixer. It's behaviour is obvious, ie limit the
incoming signal so it's you get a constant amplitude carrier and mix
it with the incoming signal to beat it down to baseband, and shows up
in plenty of designs, both before and after the Badessa patent. There
was an article in Ham Radio for September 1970 about the MC1496 double
balanced modulator, and Roy Hejhall specifically mentions it's use as
an AM detector in a similar scheme. He said that a limiter wasn't
even needed since the 1496 will limit with enough signal. The same
thing is stated in the MC1496 datasheet though you have to dig a bit
to find it since it's under the "product detector" heading. The filter
in this scheme is optional, because not only is there the 1496 example
but I've seen similar schemes with no filter. The same scheme shows
up in that fairly recent QST article about a synchronous detector (it's
been in the Handbook too), though there it's labelled as
"quasi-synchronous" and it's merely a side circuit to the main part using
a PLL. But if you look in old literature it gets the "synchronous
detector" label.

What is a puzzle is why Olberg did not reference such articles, because they were halfway there to explaining the reciprocal detector, and what is vague in his articles is what makes the RD different.

One thing is certain. That "amplify the carrier, limit it and use it as a locally generated carrier" scheme will not work with SSB, unless the original carrier is not well suppressed. And it's not going to work with CW either, since beating a carrier, as you say, against itself will result in DC and double the carrier. There'll be no beatnote. Since the RD is claimed to work on these modes, something else has to be going on.

Wow nice site. He also has some MP3's of old 78's. Just the stuff to
broadcast over your "wireless phonograph" to hear on your old Philco or
Zenith.
(In my case an old Majestic / Grunow).

When you get _Experimental Methods. . _, look at the very first few pages -- "Getting Started". You'll find a nice drawing and some other information about "ugly construction".

Incidentally, the method was first described and the term coined in the article "The Ugly Weekender" by Roger and Wes Hayward, in August 1981 QST. If you can get hold of a copy of this article, it has more about the method, as well as some other good information.

If and when you do eventually decide to get a scope -- I've been surprised to see Tek 465 scopes going on eBay for about $200. That's an awful lot of bang for the buck.

You can series and parallel any number of capacitors to get the right value. A given oscillator type works best within some range of reactance values for L and C. If you go too far outside the ideal range, stability will suffer, noise might increase, and if too extreme, it might not oscillate. The ideal range depends on the oscillator design. That being said, you can often vary L and C quite a great deal and still get adequate operation.

Real inductors are, in general, a lot more different from their theoretical ideal counterparts than capacitors are. Real inductors have considerable loss and stray capacitance, as well as being temperature sensitive. So you'll often find that a circuit works quite a bit differently if you substitute an inductor for one with different physical construction. For a VFO tank, I use only toroids wound on type 6 powdered iron material. (As I mentioned earlier, type 7 is probably as good, but I've never used it.) For VFO tank capacitors, I use only NPO ceramic. The combination produces low drift, dominated by the inductor. If desired, the drift can be compensated by replacing part of the C with negative temperature coefficient parts. Most other types of L and C have substantially greater temperature sensitivity. You might get lucky and have poor parts drift in opposite directions and more-or-less cancel, but that's poor practice and hard to duplicate. Better to design for minimal inherent drift, then compensate what's left if necessary. Toroids have the big advantage of producing a relatively small external field. That makes them much less sensitive to mounting, the influence of nearby objects, and microphonics.

One excellent reason for a crystal regen is to use it after
an upconversion stage as a simplified IF-amp/detector
with (I believe) outstanding sensitivity.

I'm interested in a crystal controlled regen also. Seeing
as I have no back issues, can you point me to a web
page?

Hmmmmmm. My RD implementation behaves like a BFO, no silence like you recall. Heterodynes 5kHz and higher with a wide IF. Olberg's hr 74/09 article says "Through regenerative feedback Q1 and Q2 form a simple oscillator operating at the filter centre frequency". When not locked onto a carrier ("nonsynchronous mode") he said, "the reference level is no longer completely amplitue controlled by the input signal". That seems to suggest that as a locked on signal becomes weak, the amplitude of the reference signal will diminish until lock is lost and rise when it becomes unlocked. He went on "but it does have signal-induced phase fluctuations", whatever that means. I do notice a tendency for the reference signal (BFO) to pull on signal strength and also on keyed carrier or bass speech energy close to the lock-in range. The latter can sound like a lf resonant belch. The narrower the lock-in range, the less susceptible it would seem, but then with no better than 50Hz tuning steps and some drift to contend with, we can't be too narrow.

>

> bfo tank from being rung by unwanted (off-frequency) signals.

It would certainly prevent them beating against the product detector's self oscillation. The filtering of the reference signal inside the RD is supposed to be fairly narrow but not so narrow as to make lock difficult. The narrower the filter, purportedly the greater the immunity to impulse noise. In my current implementation, I use a ceramic resonator paralleled by a white top 455kHz IF L-C resonator. Olberg showed just an inductor in parallel with a quartz crystal, the inductor apparently chosen to resonate with the crystal's interelectrode capacitance at the crystal's frequency. My LC ratio is much lower and is perhaps not as effective at suppressing wideband noise but I can tune for a tighter lock range than Olberg recommended.

>
> The bfo offset required for these modes, and thus non-synchronousness of
the

The "reciprocating" nomenclature seems to be related to switching the path between opposite phase legs of the product detector on the carrier phase reversals that occur with zero crossings of the modulation envelope of a suppressed carrier AM signal. Perhaps he borrowed it from "reciprocating engine" metaphor. The inventor, Badessa, did not use the term in his patent.

>
> Thinking about it now, I simply can't recall any attraction other than
> novelty ;o)

It does seem to me to be an inexpensive synchronous/nonsynchronous detector for all AM modes (and possibly NBFM) that can be easily constructed for low frequencies, eg 455kHz. I'm sure my parts cost is only about $10 compared to $150 for a kit that uses the Sony ICF2010 parts. I'd like to try a 2010 as many extol the virtues of its SD and see how they compare. My main complaint with the RD (or, at least, with my RD) is the audio null that occurs at one point in the lock range.

I would suggest the FT-817 - small, light and covers 160M - 440Mhz with 5W out
CW, SSB, FM, etc. With an internal battery pack it is just over 1Kg without
the microphone.

Hi Tom, I was waiting for a thunderstorm so I could answer your question. We finally got one.

You get maximum audio in the center of the passband as long as the regenerated carrier is in phase with the original carrier (suppressed or not). With the RD it is in phase.

It's hard to tell what lock range I get since I have a DDS local oscillator that only tines in 10kHz steps. I believe that since my RD uses a xtal, the lock range would be in the ballpark of a hundred cycles.

As far as noise rejection, I also have an envelope detector in my receiver and I can switch between it and the RD. I cannot tell any improvement on static crashes. I tried my electric shaver as a noise source and the RD may have had slightly less noise - but not enough difference to write home about.

Bob

Works for me on Win98, right from the Start Menu. My cmd line is
E:\VE3ERP.BAT. I see gwbasic.exe in the same path. I can't remember if that
came with HamCalc or whether I put it there. The bat file either needs it to
be in the same path or there has to have been a PATH command issued prior
that includes the path to gwbasic.

Hi all,
I got my new version from
http://www.cq-amateur-radio.com/HamCalcem.html . The page says it is
ver.65, but the archive has number 66. I REMed the "attrib" line in
the VE3ERP.BAT file. Now it runs O.K. under Win2K. It worked even
without that change, but an error message appeared shortly at the
startup.

>Parallel a couple.

Is there also an issue about harmonic content? ISTR there is no
significant harmonic filtering after that amp, so any replacement needs
to be operating well below its quoted maximum power output (which will
be at 1dB compression, where significant harmonic output is guaranteed).

Depending on the detailed schematic, might the input and output match
also be important? Are any filters or attenuators relying on this amp
for their wideband 50R source load or source? If there is no fixed
attenuator pad at the output, then the variable attenuator is relying on
the accuracy of the amp's output impedance (at least at high output
levels, ie low attenuation).

This might be a case for using push-pull, to reduce the even harmonics,
if you can find suitable wideband transformers. Four GALIs of some kind
in push-pull parallel might do the job nicely... but if you want to get
it as right as HP did in the original design, it ain't trivial.

I shouldn't have said that - I'm now too scared to switch on my 8640A!

385. rock candy for popcorn receivers.

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-17 08:14:52 UTC
From: The Eternal Squire <eternalsquire@comcast.net>
Message-ID: <UK6dnZEjge8Hy4uiXTWJkA@comcast.com>
Source record: 34151

Hi,

I have a question making a diplexer for a popcorn receiver:

For example, suppose I have an active mixer (AD831)
where the IF is the colorburst frequency (3579 khz).
I would then use an MK484 AM receiver chip (TRF stage
as demodulator) operating at the colorburst frequency
to downconvert from IF to baseband.

Given that lineup, does it make any sense to couple the
mixer and the TRF stages together using a colorburst
crystal, or do I need to couple them with a fully elaborated
diplexer?

I'm wanting a CW receiver, so I am not that concerned
about the crystal not being wide enough to pass voice.
Or is there something about impedance termination which
makes a diplexer far more important than the narrow
filtering which a crystal would give me?

That is to say, would a crystal work as a diplexer under
this circumstance?

Thanks for the advice in advance,

The Eternal Squire

Sick thought :) did we hams just discover the Electric Derringer?

But seriously, the best way to debug one is backwards: 1) power supply
(seeing as you need it to run
everything), 2) audio stage. If you get a cheap signal generator from EBAY,
inject a 1 kilohertz
signal into the beginning of the audio amp and be certain you get a normal
volume to your headphones.
3) Set the generator to what the VFO circuit is supposed to be generating,
and debug your mixer stage,
that's the most difficult part. Now, if the VFO is actually a bogus
circuit, I have always found a no-fail
solution: the MPF102-based VFO from DeMaw's QRP design handbook.

Good luck,

The Eternal Squire

Sentence "the very first who will F* you up is someone who is close to you" is widely known in Serbia. Also all Serbs know they are "very clever", "talented" and "nation given by God". Sad. It isn't bad to talk but it is bad and sad to spread rumors about something that you don't know, can't prove, something that you are just guessing. That is one more prove about who the Serbs are. I'm Serb too and can't say I'm proud of it. What is the way you want to see photos of the tubes and show you how wrong you are ? Then I would like to her your opinion about tube(s) "in question".

Regards,

Dragan

U Srbiji je jako poznata izreka "ko ce koga nego svoj svoga". Takodje je u Srba poznato da su "jako pametan", "talentovan" i "nebeski narod". Zalosno. Nije strasno pricati ali je zalosno tvrditi nesto sto neznas, ne mozes da dokazes, nisi siguran i baziras na pretpostavkama, sto je samo jos jedan dokaz o navikama u Srba. I ja sam Srbin, i ne mogu reci da sam zbog toga ponosan. Na koji nacin bi zeleo da ti uradim fotografije kako bi se uverio koliko gresis ? Tada bih voleo cuti tvoje misljenje o "spornim" cevima.

Pozdrav,

Dragan

This coming Sunday....

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday July 20th 2003
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society

The Analog Devices AD607 would do the trick.....it is an I.F. subsystem
that has I and Q outputs. There isn't much support from Analog Devices on
this one, so you would be breaking new frontiers.

Pete

All good points, Ian. Indeed there's no filtering after the
amplifier, so if you want to keep the harmonic content low, you will
want a decent amplifier there. Also, the output power should be at
least +23dBm if you want to have the same performance as the original.
However, I believe the output is leveled (or at least monitored), so
the output impedance is irrelevant, except perhaps on the highest
range where the source impedance may depend on the amplifier output
impedance. I could have a closer look at the schematic (and in the HP
Journal article about the 8640B) if anyone has a serious need to know
some more details.

It may have been in this group a while ago that mention was made of
the way the 8640 generates its output bands: an oscillator from about
250 to 500MHz, with digital divide-by-2 stages followed by LC filters
to attenuate the harmonics. Someone said, I believe, that there is
only one filter per octave. That is not the case with my 8640M, which
on the higher bands has two filters per octave, one for the low half
and one for the high half of the band, which are somehow automatically
switched. I didn't look into just how the switch point was
determined.

Cheers,
Tom

>

Well last night I took some double sided copper clab board and cut off
a small square. (By the way, what is the best way to cut this stuff?)
I rebuilt the oscillator on there in 'ugly' style. And it was in fact
quite ugly. It looked like something I would have done as a kid. But
it worked! Now I'm sold on it. Hopefully I can get some pointers on
improving my technique from the book.

Now I have a new question though. The circuit is a Clapp based on the
MPF102 JFET. When I compute the frequency range, it is close to the
measured range but not the same; but there appears to be some
capacitance that I can't account for, and its value seems higher than
would be 'stray'.

The circuit I'm using is basically like the one at
http://www.electronics-tutorials.com/oscillators/colpitts-oscillators.htm
in figure 2, but without the extra parallel stuff on the variable cap.
So I calculate the cap value by adding the var cap value in series
with the caps labelled on that website as cfb-a and cfb-b. (By the
way, what happens if those two aren't the same value?) Do any of the
other capacitors in the circuit factor in?

How much capacitance could my 'pill bottle inductor' be contributing?
I was careful, but not extra careful when winding it.

Are you kidding? almost all my attempted oscillators run at 0Mhz..

I usually cut PC board material with tin snips. A hacksaw also works, but it makes a lot of irritating dust.

In the schematic you mention, the "a" and "b" capacitors form a voltage divider to control the amount of signal that's fed back to the active device. If there's too much (a/b ratio too large), the waveform will be distorted and the temperature drift will probably increase. If there's too little, the oscillator will be slow to start or won't start reliably or at all.

I don't want to answer your question about calculating the oscillation frequency without some detailed thought, which I don't have time for just now. But I believe you're doing the right calculation. Note that the oscillator output is in parallel with the "b" capacitor, so any capacitive loading on the oscillator will lower the frequency. The RFC and your inductor will both present some stray C. It's nearly impossible to tell how much C your inductor will contribute. There are a couple of ways to measure it, but if you've got the other capacitances under control, you've already made yourself a test fixture for determining inductor capacitance (assuming you know its inductance) -- it's the oscillator.

Nah for 0 MHz -- have a switch labeled 0 MHz -- fed by a battery.

Its the 0.00000000000000000000000000000001 Hertz that will be a problem

All in good fun.

Seriously you need to decide on accuracy and stability first which will
dictate whether you will be building an analog, or synthesized unit.

For an analog homebrew project -- see URL:
http://www.vintage-radio.com/projects/signal-generator.shtml
Covers 150kHz to 12 MHz. For the lower frequencies -- get a hold of some of
the later solid state Heathkit Audio generator manuals.

Or from scratch -- consider the following books:
http://www.sss-mag.com/cosc.html#books

A group of local ham would like to make some simple boards that have large traces and pads. Traces are 100mils wide and pads are 150mils. It's a single sided board.
It will be cheaper to go with a silkscreen over the photo etch method? Can anyone recommend a screen kit that would work for this project. The boards are 12 inches long and 3-4 inches wide. Pre-sensitized copper clad board is very expensive.We need to make 12-15 boards.

I havn't read back to see what oscillator frequency is required.

But estimating coil dimensions is most likely to be the greatest source of error, especially at VHF. It should not be forgotten the dimensions of the tuning capacitors and the length of their connections affect the total circuit inductance.

The self-capacitance of the coil and its capacitance to surrounding parts is also of consequence.

In general, expect the resonant frequency to be several percent smaller than predicted.

If the coil is a small solenoid then use program SOLNOID3 to predict inductance. The program allows self-capacitance to be accounted for. But accuracy can be no better than the accuracy of measuring and constructing it. Take into account the difference between former diameter and the distance between wire centres otherwise for small VHF coils the inductance error may be as much as 10%.

The manufacturing tolerance on tuning capacitors MUST be taken into account. It may amount to plus or minus 20 percent corresponding to a discrepancy of 10 percent in frequency. If your oscillator is a VFO then I don't recommend a Clap. Its output always falls fairly fast with increasing frequency. You can't beat a parallel tuned circuit between gate and ground with the source tapped about 1/4 of the way up the coil.

Download SOLNOID3 in a few seconds and run immediately.

The workaround is to have a variable oscillator beating against a fixed oscillator. So you have your variable oscillator going from 30 to 42MHz (I just picked those out of my hat), a fixed oscillator running at 30 MHz, and a mixer fed with both oscillators. The output of the mixer will be 0 to 12MHz (plus some other things).

Hi John,

I need to get one of the MAX038EVKIT oscillator evaluation kits shown at the website below but can't check the price nor order it without being a logged-in member, and don't believe that would work out for a one piece hanm radio use purchase. Where/how can I just order a single unit?

Maxim has an enlightened purchasing policy and will sell at a small premium,
1 or 2 of anything in their product line direct.

Digikey sells a single unit of the chip for $24, but 25 is their
minimum order. You will have to recreate the kit with your own parts.

The data sheet shows most of what you will need.
http://rocky.digikey.com/WebLib/Maxim/Web%20Data/MAX038.pdf

Maxim is also pretty good about giving out samples but you will have
to register.

I get minimum audio near the centre. It's hard to tell where centre is with 50Hz steps. Tried reversing phase of feedback loop and got no oscillation, no audio. I'm wondering whether a phase shift network might be needed in the connection of the feedback loop to the product detector base. In Olberg's 10.7MHz version (hr 78/10), he describes a phase shift network on the input signal to the product detector. The unshifted signal also feeds the biased half-wave rectifier/reciprocating switch, as it does in the original version, which lacks the phase-shifted input to the PD.

That's what I get with my RD variant, too.

Do you hear heterodynes with your RD as you tune between stations and approach lock? In your e-mail you indicate that you hear only white noise in the absence of signal.

Oh, that's easy. You're *trying* to build an oscillator; give up on
that goal and choose an easier one: try to build an amplifier. I mean,
really *want* to build a stable amplifier. Voila! An oscillator!!

There's a mechanical switch on the slide-rule tuning mechanism.

But the true glory of the 8640 series is the way it keeps the FM
deviation constant when more dividers are switched in. Who else but HP
would have used a differential gearbox?

I think that Mega Electronics (in the UK) sells a silk screen kit. It's
intended for silk screening legends onto PCBs, but it could be used for
resist.

Where I worked 40 years ago, we made some PCBs using silk screen.

A DDS chip like the Analog Devices AD9850 will give you something close to
that. It won't quite go down to 0 MHz, though. You could just switch it off,
of course.

Looking at a cicuit, this issues seem to be
The attenuator presumably relies on the output impedance being 50 ohms
The hybrid has a gain of 16dB with an output of about +23dBm. Monitoring and AGC is separate from the hybrid, so all it has to do is provide the gain and output!
Supply voltage is 44V
There is no post amplifier filtering, so harmonics will depend on the amp.
None of the conventional MMICs seem to fit directly - it might be necessary to make up something from discrete components

Richard

> 12 MHz is easy. 0 MHz is really difficult.

If you read my original post again or at least the topic, it says 0-12 (not 0, 12) MHz. And that would mean something in the range between 0 and 12. I don't remember when and WHERE i said that i need 0 MHz oscilator. The only one who talks about 0 MHz osc is you.

Big thanks to all other people who gave me good starting points. I was thinking about some CMOS devices, but most of them are square output. This MAX038 baby looks like a dream come true!

I also need to say big thanks to Old DXer. That is exacly what i was looking for !!! A finished project. If anyone knows similar links with finished oscillator projects of this freq. range, you can simply add it in a follow up to this message.

Thank you all again!!

Hi, I re-designed a 8 el. Quagy for 70cm because I had problems with the original design. I thought it might interest to someone so I put it on www.qsl.net/ik1hge/homebrew/homebrew.html
It seems that the antenna works fine (gain looks outstanding for such a small antenna, but I can't measure it accurately), however I'd like to get some feedbacks from someone else. It's very easy to build.

Thanks
Bye
Roberto

And of course, even if such a full range oscillator was not intended
by the original poster, I'd say there often is a big difference between
oscillators in the KHz range and those in the MHz range. Obviously,
the concept of an oscillator doesn't change, but the specific design
does.

You can use resistors and capacitors to set the frequency down near
the audio range, and do your best to avoid coils down there due
to their size, while once you get into radio frequencies, one tends to
use coils for the frequency control element.

Time after time, I see people asking questions about oscillators,
and often they are coming to radio frequencies from an audio background.
So they think in terms of just scaling some favorite audio oscillator
up to radio frequencies, when a simpler solution would be to use an LC
oscillator.

Somewhere in this thread, the 8038's more recent spawn was mentioned.
Obviously, it will work over that full range, but I'm suspicious about
how good it will be at radio frequencies, as I would about any RC
oscillator. It seems a stretch to expect it to work as well at 12MHz
as at 10KHz.

I agree. But on the other hand if you controll this 8038 with another PLL synthesizer, i think the overall performance should be ok from 10 kHz to 12 MHz. I think that is the way how most of "pro stuff" works.

Zero MHz is real easy, just throw a capacitor, transistor,
resistor, tube, or any other electronic component on the bench.
There, an oscillator that oscillators at zero MHz.

For a while they were, then there was only an index, and now I'm
unable to find anything. Just yesterday, I boxed up a _complete_ set
of HPJs to move to our new site, so if there is a specific article you
need, please ask and I'll see what I can do (after the move in a
couple weeks). I have the HPJ that covers the 8640 at home, though,
and could turn part or all of it into a PDF file. Unfortunately, the
PDF would be large because it's a set of images, not text-based, from
my scanner. I also have the service manual on the 8640M, which is a
little different from either the A or B models.

Presumably it's a bit different in mine, since there is no slide-rule
tuning mechanism. I'll have to have a look.
>
> But the true glory of the 8640 series is the way it keeps the FM
> deviation constant when more dividers are switched in. Who else but HP
> would have used a differential gearbox?

In the 1970's when the 8640 was designed, we did, and people like
Collins did, but now we don't. There are very few pots or trimcaps in

our circuits these days, too, for the same reason--and there are a lot of processors of various sorts, and lots of DACs and the like. I used to think the 8640 phase noise was pretty good, but it doesn't hold a candle to what we do these days. My fun these days is in finding ways to make meaningful measurements 120dB below full scale with data from a 12-bit or 14-bit ADC. :-)

Cheers,
Tom

...

First of all, many thanks, Michael, for quite a nice summary about
regen and superregen!

A distinction between regen and superregen is that in regen, the
feedback is kept (just) below the point of oscillation, and in a
superregen, it's above, but with quenching, so that the circuit
multiplies the energy in the tank when it's gated on by some factor
depending on the feedback and the time it's left on by the end of the
gating time. A jitter-free gating time and stable feedback should
result in a low output noise level.

I believe the quench frequency will limit how narrow the detector will
be, and if one uses a high Q tank (such as a crystal) with relatively
low feedback, that will limit the gain available. During the off
time, the tank energy must decay sufficiently to track the input
signal amplitude. Is there any value in having a short time just
after the "on" period when the tank is actively quenched?

An example of a commercial use of an externally-quenched superregen is
in a radar altimiter...I think it is/was something like APN-141. It
applied the gate just once per transmitted pulse, at a time which
locked to the return pulse, as I recall. I wish I could remember now
just how they tracked changes in the return time. I do recall that it
would scan over a range of delay times from very short to relatively
long, and could track from just a couple of meters up to at least a
few thousand meters. I also don't recall for sure, but suspect they
changed the gate duration depending on the delay time, since close-in
returns are much stronger than distant ones. Shorter gates mean less
gain. That's one way to control the gain of an externally-gated
superregen.

It should be possible to build a pretty accurate model of an
externally-gated superregen in SPICE...though to limit the time it
takes to run the simulation, it's probably useful to start with an

operating frequency not too far above the quench frequency, perhaps a couple dozen times f(quench).

Cheers,
Tom

Alright, I am really utilizing these newsgroups for the upcoming hamfest. Just picked up a ts-820s. Looking forward to receiving it and reading the manuals before operation. (Sometimes I wonder if XYL has influenced me with that). I would like to know some testing equipment I will need to get this rig in flight so that I can pick them up at the hamfest. I was reading some posts that talk about tuning the rig and it sounds like fun, albeit treated with respect like all high power electronics, but also more than a simple voltmeter will be needed. Any suggestions?

IIRC, there *is* a switch in the tuning mechanism, and it switches
filters right at the midpoint of the band. I can't find my copy of
the manual to confirm that. *sigh*

Hi

Came across some notes OE3KK dated 1955 for proper control-grid modulation, where it was emphasized to use an attenuator between the driver stage and PA to adjust the drive level and swamp the RF drive on minimum modulation.

Wonder if this is mentioned in some English litterature since I receive some requests for it, and would like to mention some possible references

I've shown the notes from an old translation to Norwegian language on the pages
http://home.online.no/~la8ak/30b.htm and
http://home.online.no/~la8ak/30a.htm

> can practice. Is this feasible? Are there any other designs out
> there besides making a full oscillator?
=======
A good but simple code key practice oscillator is a single transistor
'double T oscillator' which can be found in the ARRL Handbook .
I built mine from the circuit published in the 1995 Handbook , page 26.19
It produces a 'clean' approx 750 Hz output.
I added a LM386 audio power IC to drive a small loudspeaker.
The complete circuit was built 'ugly construction' and powered by a 9V
battery.
The external Morse key serves also as the power switch.

Many moons ago I built a code practice oscillator using a 555 timer IC ,but
the tone sounded rather rough ,the output NOT being a sine wave.

A good pair of recent articles was written by Eddy Insam:
i) E. Insam, Designing Super-regens, Electronics World,
April 2002, pp46-53
ii) E. Insam, Applications for Super-regens, Electronics World,
May 2002, pp18-20
Electronics World is the UK publication, which was for many years Wireless World and finally metamorphosed into Electronics World.

Insam covers most of the key ground, ie separate and self quenching, what controls bandwidth (rate of change of the conductance as oscillation starts), why crystals are rarely if ever used (see later), etc.

Insam mentions, but does not go into any real detail on the use of SAW delay lines in super-regens. This was mentioned by Pat Hawker, G3VA, in a piece he wrote in Electronics and Wireless World (Wireless World as was), Dec 1987, p 1275. He referred to a paper by Darrell Ash of RF Monolithics:
'A low cost super-regenerative s.a.w. receiver', IEEE Trans-CE, Vol 33, August 1987, pp395-404
where better sensitivity, reduced bandwidth and better stability were claimed. On the RF Monolithics web site (www.rfm.com) you will also details of the Ampilifier Sequence Hybrid (ASH) receiver architecture, which is an alternative to using super-regens at VHF and UHF frequencies.

In his piece, G3VA also mentioned some work done by Nat Bradley, ZL3VN, on the use of crystals in super-regens (also written up in two pieces in his column in the RSGB's Radio Communication, ca. 1979 and 1980). He tried using crystal controlled receivers, but ".... did not have any great success with them. None would operate on Xtal fundamental, but a harmonic Xtal could be made to super-regenerate, kept under some control, and feed a separate detector for some results. Try that approach." The quoted part comes from personal correspondence in Nov 1999. It would seem that he was using the crystal super-regeneration stage as an amplifier, with a separate detector.

BTW the standard reference on super-regenerative receivers was and still is:
J.R. Whitehead, Super-Regenerative Receivers, Cambridge University Press, 1950.
This excellent book contains all the theory. Whitehead was at the Telecommunications Research Establishment in the UK during WW2 and played a, if

not the, key role in designing the Mk.3 I.F.F. (Identify-Friend-Foe) equipment which used a super-regen receiver. The allies built 170,000 of these units.

>In the September 1972 issue of CQ, Irwin Math in his Math Notes column had

>note that a Q-Multiplier is just a specific application of regeneration.)

I would look at it differently. A super-regen is a sampled data system. The word modulated conveys the wrong idea to me.

>Indeed, a regen is just an oscillator with controlled feedback, or
>to look at it another way, a regen is just an amplifier with positive
>feedback.
>
>So you can take just about any oscillator circuit, and by adding some
>sort of control so you can reduce things so it's on the verge of oscillation,
>you've got a regen detector. Coupling into it may be easier with some
>circuits than others. And once you've got a regen circuit, adding
>some scheme to modulate it at an ultrasonic frequency will make it
>a superregen.

It is also easy to end up with a super-regen cct by accident if trying to build a reqen cct. :-)

>Since a crystal controlled superregen is relatively rare (who knows
>why), you might want to start things by going through this sequence
>and figuring out the best setup yourself.

Time to tackle this issue. The rise time of the oscillations and quench time (when you want the oscillations to drop to zero) are both dependent upon the Q of the oscillator, which for a crystal is very high. Insam discusses this on p. 49 of his first article, and ends by saying that a 30MHz crystal may place a quench rate limit of 400Hz. Clearly this could only be used for low bit-rate data recovery.

>Someone once pointed out here that for a lot of uses you don't need ultra

>There was a superregen receiver article of his on the ARRL site,
>http://www.arrl.org at one point, and doing a search there would hopefully
>find it.

Here are the details of Charles Kitchin's. N1TEV, more recent work on
super-regens:

Dec 1997 QST 39 An Ultra-Simple VHF Receiver for 6 Meters
Article: http://www.arrl.org/tis/info/pdf/9712039.pdf (187,078 bytes)

May 2001 QEX p62 New Super-Regenerative Circuits for Amateur VHF and UHF
Experimentation (Letters to the Editor)
Sep 2000 QEX pp18-32 New Super-Regenerative Circuits for Amateur
VHF and UHF Experimentation

In the Sept 2000 QEX article Charles states that the sinusoidal quench waveform
is the reason that the receiver can detect NBFM. I believe that quench
waveform is the effect of the operating conditons where the rate of change of
conductance as the oscillations start is low. One should also realise that
this is a self-quenched receiver.

The other interesting effect is that for a logarithmic mode super-regen, the
selectivity improves as the signal to noise ratio DECREASES. Whitehead
discussed this in his book, and Charles Kitchin's resuts agree.

>Take note that most superregens use the same active element as both
>the RF oscillator and as the quench oscillator. Separating them,
>has certain advantages in trying to get the best quench, and these
>days it pretty much costs nothing to add the extra circuitry, unlike

>a certain frequency), and getting a crystal to oscillate up
>there may start being a problem especially the higher you go. Though,
>I think some work has been done with SAW controlled superregens.
>And whether it adds to selectivity is under question. Stability might
>be a factor, but then the traditional wide bandwidth has always offset
>any issue of frequency stability. Who cares about drift when a superregen's

>bandwidth would basically cover most of the 2meter band?
>
> Michael VE2BVW

So where does this leave us? For VHF/UHF applications, one has:
i) L-C controlled super-regen
ii) SAW controlled super-regen
iii) ASH receiver
iv) low-cost superhet.
For this last option, see:
I. Hickman, Super-regen or Super-replacement, Electronics World (UK), Feb 1999, pp138-143 where he discusses the use of a low cost superhet chip from Micrel as an alternative to super-regens for data transmission. See also the Micrel web site at www.micrel.com, and look for the 'Qwikwire' product details in the 'Radio Frequency' section.

HTH and that I have not written too much.

Heh. Of course a DC power supply is indistinguishable for
a 0Hz oscillator under the best of circumstances, right?

But, 150MHz. That's pretty special. What were you using
for a pass element(s) ?

Dana

> the manual to confirm that. *sigh*

From the 8640M service manual:

(talking about how the filters are switched...) "The mid-point of the
range is sensed by a Schmitt Trigger which compares a reference
voltage to a voltage proportional to the frequency tuning. On the
four lowest frequency ranges the RF signal has little second harmonic
content because of good waveform symmetry; therefore, each range has
only one filter."

It's possible that the M is a bit different in this respect from the A
and B, though it tends to be very similar to the B.

Cheers,
Tom

The 8640 article would only be out of historical interest, to see what
was in the designers' minds at the time.

I downloaded the 8640B manual from the Army site mentioned here a few
days ago, but am still looking for a manual for my 8640A (at the same
price :-)

>> >Someone said, I believe, that there is

Beg your pardon - only the A model has the slide-rule dial, but the
filter switch is probably the same.

> I'll have to have a look.

You go do that, Tom - mine's right at the bottom of a stack of HP boxes!

>candle to what we do these days.

True, but it was better than the first generation of synthesized boxes
that followed the 8640, so the less-fashionable 8640 series are still
very good value for money for amateurs. With HB crystal filters to
attenuate the noise sidebands even further, you can make good
spot-frequency measurements up to at least 144MHz (see SM5BSZ's website
- I'm currently editing an article by Leif, to appear in DUBUS in the
fall).

Feed the square output to a coil+capacitor in parallel and you'll get
a sine wave. Tune the this 'tank' circuit for harmonics of the
funamental and you can double, triple, quadruple and so on the
original square wave's frequency.

435. MRF 454 power Amplifier: Motorola AN762

Hi all,

During testing something went wrong: result no output. At first it operated flawless: a good 140 W out with 4 W in (FT817). It must have gone into oscillation because the resistors R1 and R2 were smoked. I used a transfer relay without further precautions (I know, never ever again: I will make the bias circuit switchable). Now the funny part: bias is easily adjustable as ever. Remove the load and it oscillates with heavy harmonics at about 2 MHz, taking about 3 amps. Iquiet about 200 milliamps. Both bases: +/-0.75 V. My guess: one of the finals is blown (base bonding evaporated). So I have to exchange them. Before disassembling this unit I'd like to get some advice and comments. Is it normal if one transistor fails that all output is gone? Or did something else fail (as well)? Then: if I need to buy new transistors: do I need to buy MRF 454 or MRF 458. The latter are in my actual amp (and seem to be cheaper) and said to similar but I don't have a data sheet.
Please advise,
Harke

This works pretty good at the third and fifth harmonics, but there is
no second or fourth harmonic in a perfect square wave.

440. Audio preamp for LM 4808?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-19 18:54:27 UTC
From: blyoung@hal-pc.org
Message-ID: <33cb2455.0307191054.38c7eeb1@posting.google.com>
Source record: 34057

Does anybody have a suggestion for a good audio IC preamp to go ahead of an LM 4808 headphone driver? I have been using the LM 386 for home brewed receivers up to now, but I would like to go to the LM 4808 because it can run on 4.5 volts (three D cells), and it will drive my Sony stereo phones better than the LM 386. But it is a low gain device, so I need about 70 dB of audio gain from an audio preamp. One or two IC stages, that doesn't matter. I know that the LM 3808 is a surface mount chip, but I think I can solder it OK. Thanks. Bill Young WD5HOH

A perfectly symmetrical square wave doesn't contain any even harmonics. For best results when using this technique to generate even harmonics, the square wave needs to have a longer "on" period than "off" period or vice-versa.

Last I went on that side of the lake, (April?), Active was in the
process of becoming Mode Electronics, a chain run out of Surrey, BC.

Other places on my "check to see if they're still alive" list are
Supertronix down on the West Valley Highway (just south of where
Longacres used to be) in Kent/Tuckwila?, and the surplus place
in Tacoma, Electronic Dimensions.

Works well if the ADC is linear enough and you have enough processing
gain. Maybe some day not too far down the road we'll have 20 bit and
24 bit 100Ms/s ADCs, but they're a bit rare right now.

Cheers,
Tom

IMO you are being led astray. I don't see why the emphasis on frequency multiplication. It is fairly simple to make an LC oscillator cover a 2 to 1 frequency range, or even 3 to 1. That could mean 4 to 12 MHz in one tuning range and 1.3 to 4 in another. The problem is lower frequencies. These days it is hard to find a large-enough variable capacitor for operation down in the few-hundreds of kilohertz range, let alone lower.

I know of only two ways that will cover the whole zero to 12 MHz range without bandswitching or switched filters.

One is the direct digital synthesizer DDS. Single chip DDS units are available [Analog Devices Inc] fairly cheaply, but they are tiny and require a computer or equivalent to control them. You get "perfect" frequency accuracy and stability and a sine-wave output.

The other is a beat-frequency method with two oscillators operating considerably above 12 MHz. One crystal controlled, the other knob controlled tuning from the crystal frequency to 12 MHz higher. Feed them into a double-balanced mixer (MiniCircuits) followed by a low-pass filter that passes 0 to 12 MHz, and strongly rejects the crystal osc frequency and all higher. One knob, no switching, no computer needed for control - but also much poorer frequency accuracy and stability.

Good point, John. But fortunately, I've never generated a *perfect*
square wave! :-) In practice, it's probably more accurate to say that
the even harmonics are well down on the odds. Blame it on dv/dt.

Source record: 34062

There is not much available in the 3v range that is really low noise. Lowest that you can get at any voltage is 0.9 nV/squarerootHz (LT1115, etc.). There is a 5v TI device that good to 3 nV/SqrtHz (OPA2228), but about the best you can do at 3v to 4.5v range is 8-9 nV/sqrtHz, at least in the audio range. Some low voltage op-amps specify lower noise, but usually upon further examination of the noise curves, that low noise is only at a couple hundred KHz.

I would recommend the TS924, which is a quad device. These 3v devices do not have much gain, 40 db maximum, compared to 80-120 db from other higher voltage devices, so you will need to string together several of them to get the proper gain and still keep distortion low.

I recommend the quad package so that you can use each of the four devices at a 8x gain each. This will total about 72 db for the four. Maybe use 1K input and 8.2K feedback. Keeping the input resistor to a smaller value will help reduce resistor induced noise.

Mouser carries the TS924 in both the DIP and the SOP package for a bit under $2. I like the SOP surface mount for deadbug construction use because it take ups a lot less space and because that size works really well with 1/8w resistors. I like to use #30 or #32 gauge enamel wire for hook up wire, burning the enamel off the end of the wire with a blob of solder. Stick the end of the wire in the blob so that the copper gets exposed directly to the heat.

To keep hiss at bay, I would recommend placing the volume control about 40 db from the speaker, and using high frequency gain roll off capacitors across the 8.2K feedback resistors, perhaps in the 0.0033 uF range.

Good luck and God bless!

I found my problem, the JFET in my oscillator had it's pins screwed up.
Now it's working fine, and i have a nice 40 meter receiver built. Next I
move on to the transmitter.

I was at a hamfest looking for some mylar caps for a circuit that called for them. I got several opinions on how to tell one and finall gave up. Are there any sure fire ways to identiy a cap as mylar and why are they bettter than a silver mica or others. Does anyone have a short chart comparing the characteristics? How did we get by before mylar was used?
tnx

Source record: 34068

what is it going to be used for???
audio i presume??
they are no better or worse than any other capacitor, they just have
different properties...ie silver mica is low loss (usually) at rf, where as
mylar is better for low frequencies and has a larger c for its size than
mica... (and much cheaper)..
oh they are quite often green in colour. (but not always,)usually with a
shiney appearence quite like dipped ceramics..sure way to id them is to buy
from a cataloge.ie RS. FARNELL. CPC or your USA equivalent..

Hank -

Non-polarized polyester film (Mylar) capacitors are dipped in a hard epoxy
coating material
and provides excellent protection against moisture.
These type of capacitors are intended for general purpose DC applications.

I have a couple of Astro Little Devil 11 meter amps that came out of an estate.

Wondering of anyone ever succesfully converted one of these to 6 meters?

I'm using a Ten Tec 6 meter Transverter on my Kenwood TS-450S and could use a little more "UMPH".

I could use a schematic showing which trim caps are input and which are output if anyone might have one.

Mylar caps aren't used very much. Metallised polyester are easier to find.

Terry -

10 meters is 28 to 30 MHz and 6 meters is 50 to 54 MHz.

IF this is the Astro that uses the sweep tubes that are now $ 40 to $ 50
each ... Don't bother.
That is a money pit solution ... and sweep tubes if they do operate at 50
MHz have low output.
Most 11 meter amps were built fast and cheap for a quick buck.
At best - it may be a candidate for parts.

You have probably heard that there are suitable CB amp candidates for six
meter conversion;
the problem is, this will be very model-specific and NO general statement
really applies.

If the original design was truly linear (not just by virtue of a label, but
by virtue of correct electronic bias
and stabilization circuitry) and used devices rated for operation ABOVE 50
MHz,
chances are it can be converted by changing the input and output tuned
networks,
and possibly the RF decoupling circuitry (DC power to devices).

For solid state amplifiers that I see everywhere now that the sunspot cycle
is again down,
when suitable 50+ MHz transistors are used, simply looking those devices up
in their manufacturer's
data book (or application notes such as Motorola's) will reveal an actual,
tested and proven
50 MHz amplifier circuit which would be easy to copy.

IF the only circuit published by the device manufacturer is for an amplifier operating below 30 MHz,
that's a pretty good sign the devices won't provide any gain at 50 MHz...

BTW, a good 6 meter yagi (which is very easy to build and much smaller than 10 meter beams)
will yield more dB increase for less dollars than the amplifier.

Easiest would be to move the 3.5 - 4.0 band up to
say 4.2 - 4.7, but you would have to sacrifice
the original band.

You might be able to switch components the "pad" the
existing components in and out to get both the ham
band and Mars.

Start with getting the manual and schematic from:
http://bama.sbc.edu/heath.htm

Examine the schematic and rig to determine which
coils/capacitors are switched in for the 80 and
40 meter bands. You'll see that the circuit is the
same for each band, but the values of the components
are different. Remember to do this both for the
transmitter and receiver portions of the transceiver.

Once you have a firm understanding of how Heath
switches from one band to the other, you will be
able to "functionally" design (specify what components
to use, and where they need to go in the circuit, but
no component values determined yet) for your new band,
which should start at something like 4.2 or 4.3 mHz.

The manual probably has a theory of operations or
circuit description section which will help you
to understand those circuits.

Next, you establish component values that will make
your new circuit work at the design frequency -
4.2 or 4.3 mHz.

Next, determine how you can incorporate the new
components into the rig. Are you willing to give up
the 3.5 - 4.0 range, or any other band? Can you
add a switch to switch in new components, such that
you don't have to give up any existing band?

Essentially, you need to figure out whether major surgery is required, and whether you are willing to do it.

>
> Terry
>
> WB0VQP

It's a non-starter, Terry. It could be done, but it is not
likely worth the effort and $. It is likely that the output
transistor(s) in the Astro won't play well at 50 mHz, and
the stray capacitance and inductance that posed no problem
at 27 mHz may drive you to distraction at 50.

Essentially, you'll need to change the input and output
tuned circuits. You won't be able to use the components
that are there now in those circuits, and you'll probably
need to change the transistor(s). And if you need to
change the transistors, you may well need to change the
"support" components that establish bias and stage
input levels.

I've not had experience with that specific radio, but... assuming it's a simple VFO, it should be a simple matter to tweak coil(s), capacitor(s), or both to bring the low end up a bit. If you're going to tweak coils, I suggest using a grid dip meter to find a good spot.

You should probably get hold of the manual for the unit first. Do a google search for 'W7FG vintage manuals.'

Good hunting.

<snip beat freq method>

If Tom - or anyone else - wants to do this the DDS way, there's a
0-10MHz function generator project in Australian Silicon Chip magazine,
May 2003 edition. It's a stand-alone box and delivers the following
specs:

Waveform Generation: 32-bit DDS, 10-bit DAC
Distortion: <1% @ 1kHz
Frequency Range: 1Hz to 10MHz in 1Hz steps
Frequency Display: "Sliding Window" 7-digit
(EEPROM frequency retention)
User Input: Three push buttons
Sinewave Output: 0-5V p-p adjustable, 50 ohm
Squarewave output: CMOS/TTL compatible, 50% duty cycle
Output Connectors: RCA (Cinch)

Power: 9VAC 1--mA plugpack

This project is designed to replace the earlier DDS generator described in Electronics Australia magazine August 1996. Copies of the article, or back-issues of Silicon Chip, can be ordered from http://www.siliconchip.com.au and they also have a list of kit sources online.

Eh? You probably should have switchable (band specific) output filters
to reduce harmonics to legal levels. With just one low pass filter set
around 30 MHz, when you run on 80 meters, you would have sizeable output
on 40M, 20M, 10M, etc.

Just some ideas....

Each band has a crystal oscillator that sets the band of frequencies. Change
that
crystal to a different one that will cover the frequency you want.

The next level from paper dielectric was mylar. Mylars can be epoxy
dipped usually green dipped, polypropolene is widely used orange
dipped epoxy, and the asian rim caps are brown dipped epoxy. That's
one good way to tell by the color of the epoxy.

Yes, many years ago we made downconverters for the 70cm band, we made
hundreds of boards with silkscreen method.

>
>This works pretty good at the third and fifth harmonics, but there is
>no second or fourth harmonic in a perfect square wave.

Even with an imperfect square wave, the even harmonics will have
so little energy content that it is difficult to filter those out and
amplify them...while excluding adjacent odd harmonics.

If multiplications need to be done, use a pulse not a square wave.
That way both odd and even harmonics have some closeness in
energy. The odds don't grossly overpower the evens. Unfortunately,
to get an even amplitude spread of harmonics, the pulse width has
to be short...and the shorter the width, the less average power and
thus less harmonic energy content. It's a compromise.

The best bet to achieve (relatively easily) a "0" to 12 MHz signal
source is to (as has been suggested already) make something like
a 40 to 52 MHz variable oscillator and beat it with a 40 MHz crystal
controlled oscillator. At the mixer output, run it into a lowpass
filter with a design cutoff frequency of around 15 to 18 MHz. That
way there is some decent attenuation on the stopband region slope
of the lowpass. There's a compromise on the lowpass type: If a
Butterworth it is the most forgiving of parts tolerances. If a Chebyshev,
the stopband region has more attenuation but that depends on the
passband ripple...ripple will effect the flatness of the desired output but
a low ripple value means the stopband attenuation is less. An elliptic
function could be chosen so that one of the stopband nulls is right at
the fixed crystal controlled oscillator frequency.

Just some thoughts...

474. IC706 Headset adapter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-20 20:38:01 UTC
From: R Packer II <rpackerii@neo.rr.com>
Message-ID: <J4DSa.14196$ib2.3529168@twister.neo.rr.com>
Source record: 34091

I have a Flightcom headset that I picked up off of eBay for a small penny, and I was wondering if I can interface it into an IC706 for working contests/DX/everyday ops? It isn't a mkii or anything if that matters. I know the headphone part of it can just plug in to the phones jack, but how would I modify the mic to work with it? I am willing to tear apart the mic to interface it, but I am unsure of what ohms the mic cartridge in the headset is. It has a stereo style plug on it, so I can only assume it is a powered element. Any help would be appreciated. 73!

Erk??!! Mylar is a DuPont brand name for polyester, actually.
"Mylarï¿½ is an extraordinarily strong polyester film that grew out of
the development
of Dacronï¿½ in the early 1950s."

Mylars (polyesters) are generally good for audio work. They can
contribute a small amount of distortion, but that's unlikely to be an
issue in ham work. They have higher loss (dissipation factor) than
polypropylenes, and the latter should be used in applications where
there is appreciable AC current such as in switching power supplies.
It's very hard to ID them from just the appearance. You may be able
to look up a manufacturer's part number, and if you wanted, you could
measure some parameter such as temperature coefficient, which
generally is a good indicator of the dielectric. But I submit that
it's not worth it! If you can identify it as a film capacitor (as
opposed to an electrolytic, ceramic, or mica), and the application
says that Mylar is good, then probably what you have will be fine.
Polyester and polypropylene are, I believe, far and away the most
common film caps, and polyprop should serve very nicely anywhere a
polyester is called for.

Sometimes internal construction is important; a design may call for a
"non-inductive" capacitor. Then you probably should buy the right
thing, to be sure, or at least measure the cap at high enough
frequency to see if it has significant inductance.

Cheers,
Tom

Get a CD-ROM from ARRL of the past few years QST articles. There are some pretty simple to build receivers and transmitters.

Then get yourself an ARRL handbook, it will be your best reference for a long time to come.

Since you're just begginning, start simple. Work on direct conversion receivers using SBL-1 mixers and LM386 audio op-amps. Keep them simple; once you get one working, tinker with it, add on to it. Most importantly, if it doesn't work--ask very specific questions.

NE602 front-ends are even simpler than SBL-1 front ends. Contrary to popular belief in some circles, you can still get the NE602 in 8-pin DIP, new, from Philips: the new name, for an improved part, is SA612AN. (The N suffix means 8-pin DIP.)

You can find most of the "Amidon" toroids on eBay: the key is to search for MicroMetals (the actual manufacturer). www.kitsandparts.com also sells the popular toroids in 25-count quantities, for CHEAP.

Ocean State Electronics has a lot of useful stuff. www.oselectronics.com (I think).

I'd add a copy of "W1FB's Design Notebook" to that CD-ROM and the ARRL Handbook. If you can find DeMaw & Hayward's "Solid State Design for the Radio Amateur", grab it. Check www.qrpbooks.com; they may still have a few copies.

I would suggest looking at the Cornell-Dubilier or Illinois Capacitor
catalogs (both have websites, too). There you will find out more interior
whys and wherefores of capacitor types and their insulation and
construction.

The "wound" (as in winding) type used to be aluminum foil in a paper
strip sandwich. Mylar film was substituted for paper for better
environmental performance. Other plastic film types are used such as
polypropylene and polystyrene, even Teflon. With development of
deposited metalization, the aluminum foil was replaced with direct
deposit of metal on the film...which cost less to produce.

There are some notable differences in dielectric material versus temp-
erature performance with both positive and negative temperature
coefficients possible depending on material _and_ construction. You
have to see manufacturer's literature to get full details on that.

There is no real identification of the interior construction based on the
exterior appearance, lead placement, or color of the outside. Those are
all manufacturer's choices and there is no EIA standard on esthetics.

Mylar capacitors, as all the other film types, generally have higher
insulation resistance than paper, thus they are more suitable for tube
circuits' or FETs' high impedances. High withstanding voltages (300
VDC and more) are fairly easy to get with both paper and film types,
but that also leads to large sizes.

Silver-mica (usually called "dipped mica" due to the exterior coating)
is generally better above a MHz due to higher Q...but many ceramic
dielectric capacitors (very high dielectric constant) can be just as good.
The "ceramics" can be made with "zero", positive, or negative
temperature coefficients...and the common lower-voltage bypass-use
types have a high negative tempco but are cheaper than most. All of
those have good Q at a MHz and higher compared to the wrapped
paper/film variety.

There are two basic types of wrapped (actually rolled) capacitors. One has the conductring material within the width of the paper or film...the other (almost always using aluminum foil) has each end extending out from the dielectric so that the leads can have all of the foil crimped on them. The latter results in a much lower internal inductance compared to the former and is a very important consideration for "RF" circuits.

With the miniaturization of SMT, the "co-fired" construction is leading to very small high-capacitance values where metalized ceramic plates are fired together in sandwiches. See the "Blue Cell" trademark construction method used by several, including Mini-Circuits. In some cases entire stripline structures, including capacitors, can be made as one unit.

Capacitors are chosen for a circuit depending on their capacity, working voltage, temperature coefficient, Q, insulation resistance, lead placement, and general characteristics. You should KNOW the circuit and what it needs to determine what you can use...or follow some article's description precisely, putting your faith in the author and editors. :-) [I've been both
author and editor...]

Hmmm...I'd "blame" M. Fourier for any of that, not the "dv/dt."

A different dV/dt, more specifically rise and fall times of the edges of a
"square wave" can determine the strength or weakness of harmonics,
both odd and even. Make the rise and fall times longer and ALL the
harmonics reduce in energy, approximately proportional. Calculation
of harmonic content is rather simple with a personal computer. If anyone
wants such a program, I'll e-mail it as an attachment (works at DOS level
even in Win98).

Rick-

The tuned circuits may be close enough if you change the 80 Meter heterodyne oscillator crystal. I assume you can read the frequency on the crystal if you don't have documentation. If you can find one 500 KHz higher, it should make your range 4.0 to 4.5 MHz. Close may be good enough!

The only problem may be that the oscillator circuit used for the heterodyne crystals, requires high-Q crystals. That was one of the weak points in the design of the HW-100/SB-100 series.

NE602s are indeed simple, but a poor choice for a direct conversion receiver. It's really important for a DC receiver mixer to retain good linearity and balance with large signals. Otherwise, strong AM signals will be demodulated and their audio will appear in the background (or foreground!). Doubly balanced mixers like the SBL-1 or one you can easily make from a couple of ferrite cores and 4 silicon or hot carrier diodes are much less sensitive to this problem than an NE602. In some circles, DC receivers have a bad reputation, and one reason is that people aren't aware of this problem so use inappropriate components.

The problem is particularly acute on 40 meter, which it's difficult or impossible to filter out strong AM broadcast stations before they get to the mixer.

Does anybody actually make paper dielectric capacitors any more? I thought they'd been gone for a couple of decades now.

Sure. For whatever reason, some audiophiles still want them:

http://www.welbornelabs.com/jupiter.htm

Paper caps show up in other places:

http://www.evox-rifa.com/technote_pdf/rfi_fact.pdf

Plastic film caps can be rolled into a round tube. Bob's Antique Radios &
Supplies has them:

http://www.radioantiques.com/supplies.html

These are much like the old Sprague Yellow Jackets. Similiar or identical
caps are at Antique Electronic Supply.

As far as I know, the flat oval style is only used for radial lead
capacitors. I suppose there's an advantage in trading width for height in
PC board construction.

Thanks for the info! The audiophile connection isn't surprising considering their general nostalgia for archaic technology. Let me guess -- the wax-coated ones are surely best because of the soft sound they impart. But I see that paper *is* still a viable dielectric for capacitors requiring the best self-healing properties. A quick scan of the web seems to indicate that's their remaining market. I see that plastic dielectrics are being touted for good self-healing properties, and at least one vendor uses a combination paper-polypropylene dielectric. So it looks like paper might be getting slowly pushed out. But there's no doubt they're still being made and used, all right.

I've just been lucky and not had to deal directly with components for AC mains RF suppression, except potted units.

They might no longer be made ,but many still reside in junk boxes .
With less homebrewing compared with say 15 yrs ago , they regularly appear
at club junk sales.

When considering to use them for valve (tube) based circuits I always test
them against their duty with an MFJ antenna analyser (a very useful
instrument with lots of different facilities)

One of the worst mistakes most beginner amateurs make is to aim for "small".

That takes skills you don't have. Trying to cram everything into a small package will get you couplings you don't want and will result in all sorts of problems.

You should aim for "simple", but you already knew that.

I don't think it's exactly like that.

The NE602 was manufactured by Signetics. Philips bought Signetics in 1975 from its previous parent company Corning Glass WOrks. In 1991 Philips Semiconductors became a separate company within the Philips group, and Signetics was integrated into Philips Semiconductors in 1993 to give greater product recognition in the US. From what I understand Signetics was aquired from Philips in 1995 by the Keo Pyung (KP) Group, and subsequently transferred to private ownership.

Anyway, a few years ago legend has it that there was a fire at a Signetics semiconductor manufacture plant in Korea, destroying (amongst other things) the master die and several year's worth of NE602 stocks. This is what gave rise to the rumour amongst radio amateurs already hit by dicontinuation of other mixers, that the NE602 had been discontinued.

In fact it hadn't, Philips continued production of the NE602 as part SA602. Philips also offered a less expensive but slightly inferior equivalent, the SA612. Later, a new manufacturing process was developed producing better performance and reliability, and at the same time minor changes were made to the SA602/612 circuit to improve performance. The new devices are part numbers SA602A and SA612A. The N suffix is for 8-pin DIP, D suffix for 8-Pin SO Surface Mount.

So, both the SA602A and the SA612A are still in production by Philips, the 602 being slightly superior to the 612.

Incidentally, despite the datasheet sating the internal oscillator can be used up to 200MHz, I am having a lot of success using it in a VCO covering range 140-300MHz. See some preliminary pictures of my spectrum analyser project http://www.hanssummers.com/electronics/equipment/spectrumanalyser/.

Probably. The web page says:

"A paper, foil and beeswax design for a sweet, sweet sound."

Looks about the same to me, but I'm not an audiophile.

I didn't notice any indication of which wire connects to the outer foil. Connecting the outer foil to the low impedance side of the circuit isn't critical, but I'd think it's at least as important as the presumed advantage of paper over plastic.

I have some metallic film line bypass caps from Digi-Key. They weren't specific about just what film was used, but they are reasonably compact and they don't show any leakage at 600V. I don't think there's any paper in them. Paper doesn't seem to age well. I don't know if there's really much advantage in a lower percentage of carbon. For all I know, the balance is made up with oxygen and hydrogen, just itchin' to cause mischief after a few internal arcs. But I'm not a capacitor film engineer, either.

I doubt any self-respecting audio designer would use them now, but
people restoring older gear often want to retain originality.

If by High Frequency you mean up to 30MHz, mine is quite practical and goes up to about 140MHz (http://www.hanssummers.com/electronics/equipment/spectrumanalyser/). If you want UHF then try a google for "homebrew spectrum analyser", brings loads of good links.

> powered element. Any help would be appreciated. 73!

I dealt with a similar issue when I installed the audio panel into my mobile for use with a 706 and two other radios as well. My headset of choice, being a standard telephone type, required DC bias to operate.

The essence of the problem is that, since the Flightcom's mic circuit is doubtless designed to simulate a carbon microphone element, you will indeed need some form of DC bias. The simplest method I can imagine for getting it going is to use about a 5.6 Kohm resistor, and a 1:1 audio isolation transformer. Radio Schlock has a neat little 1:1 transformer that's 600:600 ohm for about $5.

Wire the resistor in series with one side of the transformer and the mic element, and supply +12V and ground. Route the leads from the other side of the transformer into the Icom's mic input.

Alternatively, if you have more than one radio to control, you can do what I did and get an old aircraft-type audio panel. Such will easily drive your headset, and provide a nice DC-blocked audio output for the mic circuit.

I interviewed many folks for tech writing positions that required writing skills as well as a knowledge of electronics.

Those resumes with spelling and grammar errors were set aside and were the last ones considered.

My friend who interviewed folks for engineering and technician positions did likewise.

Many employment agencies throw out the resumes with spelling and grammar errors when they have numerous applications . Maybe right or wrong as they may have missed a well qualified candidate -- but that's what they do.

?? As Roy said, you probably won't find many modern paper caps.

Polyester (aka Mylar) caps come in a wide array of shapes. You can
get them as round, axial leaded parts in either molded or
shrink-sleeve packages; as rectangular-cased "radial" leaded parts; as
dipped radial leaded parts, and even (in large values) with screw
terminals. You can get them in surface-mount packages. It's really
pretty difficult to tell what's inside by the look of things outside.

FWIW, I've been conducting a long-term experiment on a couple
polyester and a couple polypropylene caps to find the self-discharge
time constant. The caps I'm testing are WIMA MKP10 polyprops and M/C
708D1 polyesters, both 0.1uF. The polyesters are exhibiting a time
constant around 4 years, and the polyprops are up in the neighborhood
of 50 years. In other words, modern caps are quite a bit lower
leakage than you'd expect from the info in sources like "Reference
Data for Engineers," and unless you are doing some very low current
work, better than you're likely to ever need, in terms of dielectric
resistance. That was NOT the case in the old days! But there are
other things to worry about. Dielectric absorption can cause trouble.
There are small nonlinearities that are a problem in very low
distortion equipment. Dissipation factor is important especially when
dealing with fairly high RMS currents. Stability can be a factor in
some designs. And of course, voltage rating and tolerance are obvious
ones. I'd guess with a little web-searching, you can find some
guidance about selecting caps with respect to these and other factors.

Cheers,
Tom

Not totally true.

We use a THA15/SD1726 (30MHz bi-polar 150w pep) producing 220w in our FM
PA in continuous duty service in the 87.5-108MHz broadcast band.

Yes, it needs plenty of drive and the heat sink require plenty of air
but at $30 USD a hit it's one economical and rugged amp.

Here it is: http://www.transmittersrus.com/shop/powerRF220.htm

I totally agree with you on the antenna.

DanTayloe: Thanks for the information about the TS924. I looked at some information on the TS924 on the web including a suggested circuit for the TS924 as a headphone driver. Why do I need the LM4808? Why not use three of the four amplifiers in the quad as voltage amplifiers and the fourth as the headphone driver? I would then need each amplifier to have a voltage gain of 16 rather than 8, and the noise situation might be somewhat worse. I see that the TS924 is capable of driving 16 Ohm phones which should be what I need. Thanks. Bill Young WD5HOH

518. Superheterodyne LO question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-21 22:12:44 UTC
From: Liam Ness <working@the.factory>
Message-ID: <kqnohvgfpjfn6vu13v7oh4233p5j403bvp@4ax.com>
Source record: 34035

I am trying to get a handle on superhet design and keep getting stuck on the local oscillator portion. I've been wading through the ARRL handbook and some other resources, but I can follow exactly how the LO signal is created. Is the signal generated entirely in the radio, or is the signal generated from the RF picked up from the antenna, or am I so off base that neither explaination is right?
As an example, if I wanted to make a single frequency receiver could I just use an external fixed oscillator for the LO signal?

TIA

Liam

>I so off base that neither explaination is right?

The word "local" gives the key. The signal is local to the
receiver... it's either generated inside the receiver, or in an
external oscillator which is tightly tied to the receiver.

Many different methods can be used to generate the LO. It could be
from a fixed-frequency crystal. It could be from a "pullable"
crystal. It could be from an LC or RC oscillator (either single
frequency, or adjustable). It could be synthesized using a
fixed-frequency crystal, a divider, and a phase-locked loop. It could
be derived (directly or indirectly) from some high-precision external
source.

If I recall correctly, one common technique can be seen in a standard
superhet AM transistor radio ("standard" some years ago, I'm sure
things have changed since then). These often used a two-section
variable capacitor. One section acts as part of an LC tuned filter,
whose center frequency is tuned to the station you want. Another
section acts as part of an LC oscillator, which creates the LO signal
at a frequency 455 kHz above the station frequency. The LO signal,
and the [preamplified?] tuned RF signal from the station, are mixed
and the 455 kHz intermediate-frequency product is then run through one
or more IF-filter stages.

Part of the trick with this design is knowing how to construct and
trim the two sections of the capacitor, so that the center frequencies
of the tuned filter and the LO oscillator stay 455 kHz apart.

[Those with more, and more current knowledge than mine are invited to
correct whatever errors I've made in this recounting!]

>As an example, if I wanted to make a single frequency receiver could I
>just use an external fixed oscillator for the LO signal?

Yes.

I really like the Philips SA604AD (http://www-us.semiconductors.philips.com/pip/SA604AD.html). It's easy to use, it's got plenty of internal gain, and it works well at a variety of IFs, from 455 kHz to 10.7 or 21.4 MHz.

I've built several decent-performing receiver sections for NBFM audio, NBFM FSK data, and WBFM (broadcast) audio with the SA604 and various filters available from Digi-Key.

Naturally, everybody that sells them appears to be out of stock right now.

A local oscillator is local, that is -- it is an oscillator in the receiver that generates a signal to heterodyne (beat) with the incoming signal to produce plus and minus difference signals, the minus usually being the Intermediate freq (IF). See URL:
http://www.see.ed.ac.uk/~gjrp/EE3/Comms/Lecture6/sld005.htm

>" As an example, if I wanted to make a single frequency receiver could I just use an external fixed oscillator for the LO signal?

Yes many a superhet has a fixed LO particularily VHF and up older designs -- used xtal or xtals -- with a crystal oscillator circuit for stability, but a tuneable LO or now a days a synthesixed LO is more common.

Have fun

The W7ZOI homebrew spectrum analyzer article is not to be missed:

http://www.qsl.net/n9zia/wireless/pdf/9808035.pdf (part 1)
http://www.qsl.net/n9zia/wireless/pdf/9809037.pdf (part 2)

You'll find this design vastly superior to the "poor man's spectrum
analyzer" projects out there that are based on CATV tuners.

It's normally generated entirely within the receiver. There are more
ways of generating an LO signal than you can count. (Unfortunately, the
ARRL Handbook's organization isn't always as beginner-friendly as it
could be.)

> As an example, if I wanted to make a single frequency receiver could I

I built the 'Poor Man's Spectrum Analyzer' a whole lot of years ago. While it does work, it leaves a lot to be desired.. The resolution isn't very good and I would hate to make any judgments on equipment performance based on it. I think it's an interesting project and I'll just leave it at that.

That's odd, since the SD1450 specifications were for the commercial FM
broadcast industry (88 - 108 MHz),
and is rated at 150 watts for 18 watts drive. Price is virtually the
ame - maybe its higher for you in UK

Many people have done well with a kit as their first project.
http://www.tentec.com/rcvrkit.htm is a reputable manufacturer with a broad line ranging from simple to elaborate. The instructions are pretty complete. In addition, you may be able to find specific designs critiqued on the Web by people who have modified them. This is an example of a report on a Ten-tec transceiver:
http://www.io.com/~n5fc/tt1340.html

Be aware that the really simple designs often have significant limitations.

As its name implies, the local oscillator is exactly that: Local to the radio itself. In other words, your first statement is correct.

> As an example, if I wanted to make a single frequency receiver could I
> just use an external fixed oscillator for the LO signal?

Sure, you could, but why bother? The only place I've seen external LO's used is in specialized test equipment, like tracking generators.

I am looking to buy user and maintenance manuals/circuits for the ITC
SA-1000 (100KHz - 1GHz) Spectrum Analyzer (circa early 1990's)
I understand that ITC was based in California and are now defunct. If you
can assist with photocopies or PDF format, please advise cost and
availability.

Thanks

The W7ZOI project is very interesting. I'm interested in what ways you think it's superior to the poor man's spectrum analysers based on CATV tuners? The latter surely have greater frequency coverage. But in what ways are they inferior and can you quantify it?

A spectrum analyser is simply a frequency-swept receiver with a
dB-scaled output to a screen. To give meaningful results, that receiver
must have a very high dynamic range with very low spurious responses.

The problem is that real incoming signals and the analyser's spurious
responses all look very much the same on the screen. When you can't
trust what the analyser says, it becomes very hard to understand what's
really going on.

As with lots of beginner-level test equipment, it sometimes needs an
expert to understand it!

CATV tuners and low-level NE602 mixers are simply not the building
blocks for a high dynamic range receiver. The W7ZOI design uses much
more appropriate building blocks so its readouts are much more
trustworthy.

>and can you quantify it?
>
Very easily, in the same ways as you test a receiver for strong-signal
handling.... but most graphically by looking at the same spectra with
two analysers side-by-side. The one showing fewest signals is the one
you can rely on most.

Hans,

Looks interesting. Back in the early '90s I built a similar project,
described in Electronics Australia magazine some time in 1992. It used a

TV tuner as the front end and an NE602 as the converter, and displays the signal on any old CRO.

Strangely, I only just got it out of hiding a few days ago and fixed a fault with one of the rotary switches. It hasn't been used in many years but I recently gave away my AM/FM tuner, and I remembered that this Spectrum Analyzer has the neat ability to tune in and play FM radio, which is why I bothered to get it going again.

It covers the ranges 88-108MHz, 138-225MHz and 470-870MHz which as you can see is discontinuous. This is because of the tuner, but nowadays you can get tuners that don't have gaps in their coverage.

Electronics Australia no longer exists, sadly; it closed in 2001 after an illustrious 80 years or so, having begun as "Radio & Hobbies" in the '20s. However, reprints of almost all articles are available from http://www.siliconchip.com.au for about AU$10.00

Did I miss something here? I thought this was the
'rec.radio.amateur.homebrew' newsgroup, and not the
'rec.strictly.correct.grammar&spelling' group.

Are we really so damn petty that we must carry on like spoilt little brats
just because his spelling or grammar is not perfect? Is that what our hobby
is all about? No wonder amateur radio is dying out.

Get a damn life! Yes, OK, his spelling and grammar was annoying, but so is
more than half of the people who post to newsgroups. I don't recall
absolutely correct spelling & grammar being a mandatory requirement for
entry to internet newsgroups, or amateur radio for that matter. And what
the hell has his resume got to do with a posting in a newsgroup? I wasn't
aware that he WAS applying for a job here!

Grow up, please, and get a life outside your office of divine intervention!

73's and very best wishes

Martin, VK2UMJ

PS - I sincerely hope my spelling and grammar met the high standards of this
newsgroup.....

or, should that be: i sinserley hope me speling and gramar are good enuf for ya news group, mate....

I used two SA602A mixers in my design (see
http://www.hanssummers.com/electronics/equipment/spectrumanalyser/) and get
about 60 or 70dB of on-screen dynamic range. The SA602A approach does have
the advantage of similicity, at the cost of reduced performance. I use one
SA602A with the on-chip oscillator as the VCO swept from 145 to 290MHz with
145MHz IF output. The 2nd SA602A has 153MHz fixed on-chip oscillator and
mixes down to the 8MHz 2nd IF.

Spurious responses in my analyser from strong signals aren't usually a problem except at the upper end of the frequency coverage. The W7ZOI analyser covers 0-70MHz, mine 0-140MHz. It would be very interesting to compare my design against a W7ZOI analyser over the same frequency range, i.e. place a 70MHz low pass filter ahead of my analyser. I suspect spurious reponses would be comparable, but on-screen dynamic range somewhat less in my analyser.

My analyser Mk2 is already under construction and will aim to provide masses more features, greater coverage, and improved dynamic range performance.

What if you don't have another analyser ;-) Part of my intention with my simple analyser was to build something straightforward but still extremely useful, and do so without access to much other test equipment. When I have the Mk2 up and running it will be interesting to compare.

A number of the MicroChip MPs have 16-bit internal counters that claim to run as high as 50 MHz. The carry out of that counter could be used to cause an interrupt to extend the number of bits in the count.

But you would need to precede the count chain with a gate of known and accurate count-window duration. I've thought about the subject and would try a 74AC-series flip-flop as the "gate". The gating control signal would be applied to its DC-reset. A 74HC4060 running with a "32" kHz clock crystal could provide the gating signal. Properly biasing the flip-flop's clock input might result in fairly good sensitivity.

These MicroChip MPs have a pulse-width-modulated [PWM] output, but it's only 8- or 10-bit resolution. It could be dithered for more resolution, but that would require an even greater time-constant in the AFC applied to the VCO - probably intolerable. A simple, inaccurate, 8-bit D-to-A chip might be used for rough AFC voltage, with interpolation using the PWM.

WARNING: All the above is just hand-waving.

Source record: 33958

Anyone know of a PIC-based frequency locked loop for VFO control? I'm looking for something that can be programmed with a frequency word, and then it aquires and maintains the frequency. I've seen frequency 'stabilizers' but most of them just hold the frequency once it's been manually set. There are also PIC-assisted DDS designs, but these are more complex thatn I want, use more power then I'd like, and are not as clean as a simple voltage controlled oscillator.
It seems to me that the PIC should be able to measure the frequency, determine the error, and operate a very simple charge-pump/VCO to put the frequency where it wants.

Why not go for the minicircuits +14dBm high level mixers ? ... their quite lossy (around 9dB loss) but that can be over come. They do need a fair bit of LO drive though (50mW) but that's no real problem these days, a couple of +18dBm MMIC's (ERA's etc) in push pull mode should guarantee that level of power and hopefully give you 3db more than needed so you can use 3dB pad's around the mixer.

Tnx, it's certainly one of the things I'm considering. That's more effort
than an LC tank on a couple of SA602 pins. But I guess for higher
performance you need higher complexity.

Given that you have a PIC available for the job, why not let it do a phase-locked loop instead of just a frequency locked loop? The key difference in implementation is the number of bits you need to actually deal with in the counter, but with the control you want to exercise, you probably already were going to have to deal with quite a few bits. The PLL (properly done) should have significantly lower spurs than a FLL. Depending on the resolution you want, you may be best off doing a "fractional-N" implementation. Wish I had lots of time on my hands; it would be a fun thing to work on! I recall thinking about something _very_ similar not long ago. You can also get very low power, tiny PLL chips that do almost everything for you, including fractional-N (though not frac-N the way I'd do it with a PIC). I could probably be available for some off-line consultation with more details about my thoughts.

Cheers,
Tom

I've seen a couple of MCU-controlled "Huff and Puff" stabilisers on the web.

You'll find a couple here:

http://www.hanssummers.com/radio/huffpuff/contents.htm

As I said in my original post, there are plenty of 'stabilizers' available for the taking. I have also seen a few PIC frequency counter implementations that don't need any external gating. There are also plenty of PLL chips which would do the job. However, I have not seen a software application for the PIC that does it all without (hardly any) external hardware...this should be possible.

What I want to do is create a tiny, low-power, stable & accurate HF frequency source module. I think I can implement it with 2 packages...the PIC and a VCO made out of biased-up CMOS inverters. I want to be able to 'hard-code' a frequency in some cases (fixed-frequency oscillator), or send an arbitrary frequency word for variable frequency control in other cases (VFO). This would be a very useful 'building-block' for making HF communications gear.

The important factors for my applications are good tuning resolution, reasonable lock-up time, and minimal phase noise. Of course, defining 'how good is good enough' is somewhat subjective. Whether it's done as a PLL or an FLL is somewhat semantic as most PLL synthesizer's really don't control the short-term phase real well anyway.

Good point. There are lots of functional alternatives, like the SA615D
(in stock at Arrow Electronics). Sounds like an even better chip than
the SA604.

Apart from what Ian said, it's also really important to have a stable
LO. If you don't -- i.e., you're relying on an inadequately-stabilized
cable TV tuner -- you can only tell if a signal is present or absent.
You can't tell much about its stability and noise level, or look for
close-in IMD products. Narrow resolution bandwidths require stable LOs.

I haven't used a W7ZOI analyzer myself, but it ought to be at least an
order of magnitude more stable than any CATV implementation. It would
indeed be interesting to see a spec-for-spec comparison between the two.

Either way, they make great educational projects. :)

I have used the TS924 as a headphone driver and it works fine. I have usually used two stages though, one to drive one ear piece, and the second to drive the other. 16 ohm headphones really are 8 ohms if both sides are driven from the same amplifier.

However, you could probably get away with what you are talking about though, using one stage as a 1x gain headphone driver, and each of the other three stages as 16x gain stages. This will have the effect of increasing the distortion, although probably not to a noticeable degree.

I like using a 3v supply. Operating at a lower voltage saves power, and as an headphone amplifier, it limits the maximum loudness that a signal can appear at into your headphones, which is still rather loud.

Mine is at http://homepage.eircom.net/~ei9gq/stab.html
Have a look at Hans Summers and Richard Hoskings web-pages.

> It seems to me that the PIC should be able to measure the frequency,
> determine the error, and operate a very simple charge-pump/VCO to put the
> frequency where it wants.
>
> Joe
> W3JDR

What you are describing is a conventional PLL. PIC based
stabilisers or 'frequency locked loops' usually have very
long gate times for counting the frequency and a fairly
narrow frequency control range. My circuit uses a 100mS
gate time and a control range of +/- a couple of KHz.

If you want to cover a larger frequency range with your
VCO, you will need to use a much shorter gate time to
keep tight control of the VCO frequency. This will
increase the tuning steps and will also increase the
phase noise on the VCO output. You soon run into the
the same trade offs and compromises that you get with
any PLL design.

A PLL/DDS combination seems to be the best way to
go. I recently built a 21MHz VFO for a 10M transceiver.
The 21MHz VCO is mixed with the output from a 17MHz
crystal oscillator. The resulting 4MHz signal is
phase locked with a 4MHz signal from an AD9835 DDS
chip. The DDS is controlled by a PIC16F84. I use the
10M rig to drive a homebrew transverter for 144MHz.
I am delighted with the results. The RX is free from
the usual birdies you get with a DDS VFO. The phase
noise is low enough that I can operate within a few
KHz of some very strong local stations on 2M SSB.

Short-term phase stability almost always lies in the VCO design with
some disturbance possible by an incorrect loop filter. That has little
to do whether the VCO is used with a PLL or DDS.

To be phase-stable (i.e., reduce short-term jitter), the VCO supply rails
should be bypassed adequately well up into the RF range of the VCO
and the control voltage line absolutely free from any loop-induced
pickup almost to the VCO's RF range. Iron powder or ferrite beads,
even slabs of the stuff, can halp on the control line. Stability also
involves using whatever active device in the oscillator at its optimum
lowest-noise point...that's device dependent and not all manufacturers
supply such data.

In truth, I've never had experience with the PLL or DDS dividers as an
integral part of the frequency control determining processor. I've always
had to work some to make the external-divider kind lay down and be
nice. I would imagine there's more fun and games with a combined
type using a Microchip processor being both controller and divider. :-)

"Meaningful results" are subjective to the hobbyist.

NO analyzer means NO results.

If I were designing a spectrum analyzer for the electronic instrument
market, I would shoot for at least meeting Hewlett-Packard Agilent
or Rhode&Schwarz specifications...R&D budget willing. That's a bit
steep for the hobbyist area.

>The problem is that real incoming signals and the analyser's spurious
>responses all look very much the same on the screen. When you can't

>really going on.

Sigh. A spectrum analyzer, almost ALL of them, is one of the easier
instruments to characterize from the outside, using other instruments.
Frequency span, logarithmic linearity, passband of the final IF are all
relatively easy to determine from the outside.

So what if a spectrum analyzer isn't "perfect?" It is much, much
better than having NO spectrum analyzer.

The majority of spectrum analyzer input signal levels are most likely
to be UNDER -10 dbm. That input level is not - generally - going to
cause all kinds of "imperfections" in the viewed spectrum.

>As with lots of beginner-level test equipment, it sometimes needs an
>expert to understand it!

I disagree. There are any number of application notes free for the downloading on the Internet, from Agilent they are copies of older (two decades at least) FREE paper application notes. Agilent also has free application notes on the basic building blocks within an analyzer and much information on the characteristics of those blocks.

>CATV tuners and low-level NE602 mixers are simply not the building
>blocks for a high dynamic range receiver. The W7ZOI design uses much
>more appropriate building blocks so its readouts are much more
>trustworthy.

Yes, its possible to "conquer" the dreaded too-high-signal IM mountain peaks with high-level mixers and higher-milliWatt first LOs. See Mini-Circuits' catalog as one place for modules.

I haven't seen the "W7ZOI design" so I won't critique it at all. Having used spectrum analyzers for about 4 decades, the high-input-level IM bogeyman seldom goes "boo!" for most spectrum observation. That includes transmitter output monitoring.

>>and can you quantify it?
>>
>Very easily, in the same ways as you test a receiver for strong-signal
>handling.... but most graphically by looking at the same spectra with
>two analysers side-by-side. The one showing fewest signals is the one
>you can rely on most.

Have you priced the used spectrum analyzers lately? Do you expect others to have ready access to "another" spectrum analyzer?

In checking my own little special-purpose IF strip Sweeper (a quasi-spectrum-analyzer), I am fortunate to have a pair of H-P rotary step attenuators (salvaged, checked for calibration by another) to determine if the Log response curve of the Analog Devices chip is correct...rather very basic stuff. Unfortunately, the accuracy of the external attenuator is about the same as the AD accuracy. I'd love to have a Weinschel Precision Bench Attenuator to use as a comparison, but don't, can't afford one.

I do have a very good pair of H-P signal generators (very much previously owned) which have been put in order by a good friend of mine. With the help of an outboard lowpass filter (easy to make) which is also characterised by response testing using a linear detector, I can guarantee an RF signal with all harmonics down 60 dbc. The RF power output of those generators is also separately characteriseable/calibrateable within 2 db of absolute level at the high-power output (0 dbm) all the way down to -120 dbm, probably lower. The lower levels are determined by a waveguide-below-cutoff internal attenuator which hardly ever jumps out of calibration unless the mechanicals get goofy. The Weinschel attenuation standard uses the same basic below-cutoff principle.

With all of the above (two generators, overlapping ranges) I can absolutely guarantee a true "two-tone" testing setup for an analyzer to determine what the 1 db or the 3 db IM values are of any receiver front end. So far, I've never ever seen any cause for concern with any input level up to -10 dbm. Have I ever done any such? Of course, even checking out a used (and rare) Tektronix spectrum analyzer plug-in on a borrow.

I have YET to encounter any receiver input that goes higher than -10 dbm equivalent input with the one exception of being within two blocks of local AM broadcast station KMPC pushing 50 KW into their antennas. I'm sure there are all kinds of "exceptions" to that and I'm sure there will be commentary coming back on that. :-)

I'm not going to get in about the relationship of sweep rate and final SA IF resolution...which are VERY important in SA work, particularly in relatively narrowband observations. Close-proximity signals can "hide" if wide resolution IFs are in place...that "hiding" visible at input RF levels
well below ANY intermodulation distortion level. The resolution aspect of practical SA design is a separate matter but should not be forgotten..

When push comes to shove in all this, I'd say that SOME KIND of spectrum analyzer is a LOT better than NONE. EOF.

I don't completely agree. there are several ways to skin this cat. One might be to implement a simple R-2R D-A converter in the PIC to do coarse frequency tuning according to a lookup table, and let the 'huff & puff' stabilizer do the fine corrections. No different than manually setting the tuning capacitor on the VFO and then enabling the stabilizer.

Having said that, there are PIC firmware designs that implement a 40+ MHz counter with 10hz resolution and 100 msec count interval. Combine this with a simple charge pump, and I don't see an FLL with any worse performance than a hardware PLL. Admittedly it's not as good as a DDS for resolution/speed, but it might have advantages for simplicity, power consumption, spectral purity and cost.

Bottom line is, I know most of the other ways to generate a clean & stable programmable RF source. What I wanted to find out is if anyone had done it with a PIC and little else. You came close with your stabilizer, but it can only stabilize, not acquire.

Joe

The W7ZOI analyser uses a mini-circuits VCO. I couldn't find any stability
data on the minicricuits website, do you know of a source?
I suppose oscillator phase noise is also important. I'm interested in why a
minicircuits VCO should be an order of magnitude more stable than a CATV or
UHF TV tuner's VCO? I have a UHF tuner here (470-862MHz). The tuning voltage
(approx 1-25V) is stabilised by a simple zener diode arrangement. Even when
left on for hours tuned to a TV station, no re-tuning is necessary. As far
as I can tell there is no AFC employed.

Oscillator phase noise will show up as noise sidebands on the signals you're measuring. They'll limit your ability to use your spectrum analyzer to judge the noise that's really coming from the signals. As a very good and professional engineer who spent a number of years designing some of the best commercial spectrum analyzers made, Wes most certainly paid a great deal of attention to phase noise and dynamic range, two of the most important potentially limiting factors of spectrum analyzer performance.

I'm an amateur, not a professional, but have paid my dues in this area. I have helped develop, and have built and used, two generations of HF (0 - <100MHz) spectrum analysers of the NE602 persuasion. Then a basket-case Texscan 0-1GHz box came along which I rescued and used for VHF work. That was followed by the HP-141 series analyser which I'm currently using (and can now be bought for much less than the price of a new rig). I also developed a 0-1.5GHz tracking generator for the 141 boxes. Through friends, I have some limited access to modern professional equipment, and know how to use it.

My experience with the NE602 type is that it's great as a "fun" analyser, but you can very quickly outgrow it. Yes, it will give you general indications, like "Is that oscillator working?" or "Is that final output stage generating harmonics?" Those indications even have some numbers of MHz and dB attached.

> NO analyzer means NO results.
>
Of course I'd rather have that much information than no analyser at all. (Len, if you happen not to mention something that is completely obvious, I still assume that you're completely aware of it. Kindly extend the same courtesy to me.)

But once you have a "fun" analyser giving you basic indications, it inevitably draws you into asking more searching questions, like "How much of a harmonic problem do I really have?" That's where fun analysers come unstuck, because you don't know how much of those indicated harmonics are real, and how much is being generated in the analyser itself.

An important practical crunch point for amateurs is "Does this transmitter meet the FCC requirement for 60dB minimum harmonic suppression?" Now you discover the big difference between 60-70dB on-screen dynamic range, and 60-70dB *spurious-free* dynamic range. The first is easy - the second is damned hard to guarantee in a HB design.

If you get to that point - and many people will - then you'll wish you'd taken the extra trouble to build an analyser that you could trust a little more. The NE602 type categorically will not hack that kind of problem, because the equipment under test is probably much cleaner than it is! The W7ZOI type may just do it, with care, and the same is true of the 141 generation. Only the best modern analysers will ace the problem without needing careful attention from the user.

The simple rule of thumb is:

1. If the performance of your test equipment is better - in whatever ways are important for the measurement in hand - than the performance of the equipment under test (EUT) then the results will be reliable enough for amateur work.

2. If your test equipment is comparable with the EUT, you'll get useful indications.

3. If your test equipment is worse than the EUT, what you're actually testing is the testgear itself! You'll learn nothing useful about the EUT, and may actually be misled.

So aim for zone 1, settle for zone 2 if you must, but stay out of zone 3.

That comment was mostly to make the point that the cleanest display is the most real.

The absolute standard of comparison is the perfect spectrum analyser with no spurious responses. That is an *idea* to which anyone has ready access, any time.

Before I ever had a real spectrum analyser, I got a lot of good mileage out of thinking "Now if I had a spectrum analyser, what would it probably be showing me here?" That isn't empty dreaming - it's a highly *practical* way of focusing your thinking on a problem in the here-and-now.

When I built the first "fun" analyser (which had to wait until the hardware collection had expanded to include a good oscilloscope) I found it quite disappointing, because it still wasn't showing me reality. I was still having to think "Now if I had a *good* spectrum analyser, what would it probably be showing me here?"

Over the years, more and more of the mental testgear has been changed into hardware, but the mental spectrum analyser still gets switched on quite frequently - it has instant warmup and it also works very well in the bath and, er, the other places where I do my best thinking!

Out in the workshop, the real hardware adds real-life numbers to the ideas, and also checks that there isn't anything happening that I hadn't thought of.

That's not the point. You are talking about the availability of information, which is not in dispute. I am talking about understanding and applying it.

By the time you've absorbed the available information - especially the information about the *imperfections* of spectrum analysers, so you can understand how much of what you see on-screen is real - you're not a beginner any more. It will have been a useful learning experience... but perhaps not the one you'd have chosen right then.

Being a beginner in any area is hard work. When you're ttrying to learn what it's all about, the last thing you need is to have to fight poor equipment as well. Musical instruments are very much the same - so-called "beginner" instruments are actually quite hard work for anyone to play; in contrast, a better-quality (read: expensive) instrument feels almost like it's playing itself.

Unfortunately, budget reasons mean that beginners will almost always have to learn on instruments (test or music) that are hard to use. We have to accept that, but for heaven's sake let's not pretend to make a virtue of it!

In this particular case, there does exist a very good, reliable, second-level design (the W7ZOI). It's a little more expensive to build than the entry-level stuff, but not significantly more complex. It's very well designed, so while you're building it you'll learn some very useful things from a top amateur (and former professional) RF designer. It's also modular, so you can build it in stages, and upgrade various parts as and when you want.

Bottom line: having played with the entry-level NE602 stuff myself, my advice would be:

* If you only want a "fun" analyser, then go for it and have fun.

* But if you want the analyser as a tool to help you develop good radio gear, go direct to the W7ZOI design.

For a VHF/UHF HB design - which is obviously going to be a lot more complex, and really is an advanced project - search Google for: "S57MV spectrum analyser" (without the quotes, and also look for the American "analyzer" spelling).

This is an intriguing discussion
The problem with a FLL will be as Joe and Ed say - that to get reasonable resolution in a FLL , you have to count a lot of pulses and this takes a while. You are comparing one count to the next - ie one count is equivalent to the reference, while the next count is equivalent to the VCO signal. In my design (which is based on Ed's originally) the gate time is 100msec, which means the comparison freq and therefore resolution is about 10 Hz, and therefore the lockup time is pretty slow. I presume it would be possible to have the loop capture lock, but I have not explored this. The loop filter would have to be carefuly designed and I suspect lockup time would be pretty long. I think a better idea would be as Joe says to have the coarse resolution set by a DAC and a coarse tuning varicap without any loop. The fine resolution could then be set by a second freq locked system with a swing of say 5 KHz as in our current system. You would have to have a voltage tunable VFO which means phase noise might not be so good.

I have been thinking about an alternative for HF, which is somewhat more complex, but should give excellent phase noise performance. I would use a microwave synthesizer usin DDS/PLL techniques for say 1000-1500 MHz
See http://www.qsl.net/ke5fx/synth.html for a suitable design. This could then be fed to a programmable divider - a second LMX2326 could be used with the main divider output being the output of the synth. The rest of the second PLL chip (reference divider/phase comparator etc) would not be used. The programmable divider is set to give an output anywhere in the HF (or VHF for that matter) spectrum as desired. The phase noise performance of this synth at microwaves is in the order of -90dBc/Hz at 10KHz offset.Dividing it from say 1200 MHz to 30 MHz would improve this by 20log N where N is the division ratio to give phase noise of better than -130 dBc/Hz at 10 KHz offset, with almost infinite resolution and digital settability. The only downside is computational overhead for the processor, but this shouldnt be a problem with modern micros. Current drain could be reduced over the current design when the new AD DDS chips become available (AD9951 etc) Anyone have any comments?

Richard

> itself.

I think it does much better than just give general indications. It certainly has opened my eyes to a whole new world inaccessible to me before having the analyser. It's comparable to the change in my hobby life when I aquired my first oscilloscope. You still enjoy the hobby with no oscilloscope, but when you get one you feel like you'd been blind before, and can't imagine life without it.

The other day I looked at the 39.5MHz IF in an old television tuned to a UK TV station signal. I could see the video and sound subcarriers clearly identifiable. Tuning the TV I could move the signals out of the Surface Acoustic Wave (SAW) filter skirts and get a good idea of the shape of the filter's response curve. Before I might have read about that stuff in theory, now I can actually see it!

Under many cases it will be possible to identify any spurious signals generated within the analyser itself. The input attenuator (in my case 0-63dB in 1dB steps) allows quite accurate measurement of the magnitude of frequency components, and also allows reduction of strong signals. In many cases this can be used to eliminate many of the spuri.

Or, if the signal being monitored is a VFO output for example, or another variable frequency source, changing the frequency will often identify the spurious signals. For example I might increase the VFO frequency, causing the fundamental frequency peak to move left to right on the screen. If I see some other peak move in the opposite direction, or if I see a peak moving across the display very quickly, I know I've seen a spurious response.

Much of the spurious response problems come at the high end of the frequency coverage range. For lower frequency work one could insert an additional

easily-constructed low pass filter and eliminate much of the problem.

So yes, no doubt the more effort you put in and the more complex the spectrum analyser, the better the results obtainable. But even with a simple analyser there's so much you can do.

I could be wrong but I thought the FCC requirement was 40dB minimum harmonic suppression, or 30dB for transmitters with output powers 5W or less? That's well within the range of even a simple spectrum analyser. I doubt I'd have any problem ensuring an HF QRP rig met FCC requirements with my analsyer.

I'm already working on my Mk2 analyser. Not because I'm unhappy with the measurements of the Mk1, but because I had so much fun with it, ending up building it for its own sake, and not ready to stop having fun yet.

Not sure I agree completely - if the EUT is *supposed* to be in your zone 3, but is not functioning properly, then even a simple spectrum analyser could help you find the fault. It wouldn't help you make precise receiver

performance measurements on it when you corrected the fault, but would help with diagnosis.

Don't forget the W7ZOI analyser covers 0-70MHz only. You can double that with a NE602 design. Nevertheless I liked the W7ZOI analyser a lot.

I just tried the suggested Google search, and came up dry -- using
both spellings: analyzer/analyser. Since I cut-and-pasted "S57MV"
from your post, I doubt that it was a spelling error.

Any suggestions?

Sorry, it was S53MV. A lot of the older information has disappeared off the web, and is now only to be found on the site of VHF Communications magazine where SM3MV's original article appeared.

http://www.vhfcomm.co.uk/articles.htm

Since the article is said to be too big for the web site (and the web articles have no diagrams anyway) it seems that you cannot learn anything useful about this excellent project without buying a back-issue of the magazine :-(

Has anyone got any data/information on the
MSM5525RS chip?
It was manufactured by Oki in the early 1990's
but sadly is obsolete now.
If anyone has a good one gathering dust , please let
me know as I would like to purchase it.
I would also like to know if it is functionally same
(pin for pin) as the MSM5525.
Any information or leads would be greatly appreciated.

Anybody have any suggestions for commercially-available SMT ICs which could be used to put together a physically-small compressor / speech processor design? I'm thinking of something small enough to be installed in-line with a standard 4-pin microphone plug, no more than perhaps 3" long - or perhaps even installed inside a dynamic or electret hand-mic housing. Low power (run off of the rig's 9 VDC supply to the electret mic if possible).

Seems to me that it'd require a preamp stage (SMT fixed-gain instrumentation amp would do?), an AGC/VCA arrangement, and an output driver and attenuator.

Richard,
It's an intriguing idea for applications where very high performance can be paid for with circuit complexity, power, & cost, but I was looking for something extremely low power and simple. I still believe my idea can be implemented with a PIC, a crystal, and a hex CMOS inverter package that implements the VCO, buffer, and charge pump.

This is an intriguing discussion
The problem with a FLL will be as Joe and Ed say - that to get reasonable resolution in a FLL , you have to count a lot of pulses and this takes a while. You are comparing one count to the next - ie one count is equivalent to the reference, while the next count is equivalent to the VCO signal. In my design (which is based on Ed's originally) the gate time is 100msec, which means the comparison freq and therefore resolution is about 10 Hz, and therefore the lockup time is pretty slow. I presume it would be possible to have the loop capture lock, but I have not explored this. The loop filter would have to be carefuly designed and I suspect lockup time would be pretty long. I think a better idea would be as Joe says to have the coarse resolution set by a DAC and a coarse tuning varicap without any loop. The fine resolution could then be set by a second freq locked system with a swing of say 5 KHz as in our current system. You would have to have a voltage tunable VFO which means phase noise might not be so good.

I have been thinking about an alternative for HF, which is somewhat more complex, but should give excellent phase noise performance. I would use a microwave synthesizer usin DDS/PLL techniques for say 1000-1500 MHz
See http://www.qsl.net/ke5fx/synth.html for a suitable design. This could then be fed to a programmable divider - a second LMX2326 could be used with the main divider output being the output of the synth. The rest of the second PLL chip (reference divider/phase comparator etc) would not be used. The programmable divider is set to give an output anywhere in the HF (or VHF for that matter) spectrum as desired. The phase noise performance of this synth at microwaves is in the order of -90dBc/Hz at 10KHz offset.Dividing it from say 1200 MHz to 30 MHz would improve this by 20log N where N is the division ratio to give phase noise of better than -130 dBc/Hz at 10 KHz offset, with almost infinite resolution and digital settability. The only downside is computational overhead for the processor, but this shouldnt be a problem with modern micros. Current drain could be reduced over the current design when the new AD DDS chips become available (AD9951 etc)
Anyone have any comments?

I don't completely agree. there are several ways to skin this cat. One might be to implement a simple R-2R D-A converter in the PIC to do coarse frequency tuning according to a lookup table, and let the 'huff & puff' stabilizer do the fine corrections. No different than manually setting the tuning capacitor on the VFO and then enabling the stabilizer.

Having said that, there are PIC firmware designs that implement a 40+ MHz counter with 10hz resolution and 100 msec count interval. Combine this with a simple charge pump, and I don't see an FLL with any worse performance than a hardware PLL. Admittedly it's not as good as a DDS for resolution/speed, but it might have advantages for simplicity, power consumption, spectral purity and cost.

Bottom line is, I know most of the other ways to generate a clean & stable programmable RF source. What I wanted to find out is if anyone had done it with a PIC and little else. You came close with your stabilizer, but it can only stabilize, not acquire.

Dear sir,

As I understood that a regenerative radio has a feed-back loop at the detector stage, while Q-multiplier has it at IF strip. Has any body tried the feed-back loop at RF stage itself.

I'm thinking of homebrewing a "tunable preselector" with a very narrow bandwidth. If we can implant the Q-multiplier concept into the tunable preselector, it should be very much cheaper than building one from a combination of coroidal cores to get the best Q factor.

Best regards,
Amin

I work with Atmel AVR chips at present - I dont think there is any clear advantage over the PIC's - it is just that I am up to speed with a development system etc.I would be interested in working on such an idea. The current VFO counter stabilzer already has much of the software and hardware developed - eg the LCD interface etc. The system would be simple enough if it worked to have a dedicated VFO for each band of interest, selectable by software. I was thinking of using a coax transmission line for the resonator.
In the stabilizer design, the "charge pump" is simply two diodes from two I/O lines, buffered by a voltage follower
I imagine that lockup time will be an issue, especially if you want the system to be tunable ala an amateur rig.
I guess there is no reason why you need to count the full resolution of the signal for the FLL. An 8 bit count should be enough, in which case you could use the controller's inbuilt counter without a prescaler, depending on the VFO freq. This should speedup lock time. I guess you could even have an adaptive lock algorithm in software with a progressive increase in resolution.
It might suit my quest to build a low power ultraportable SSB HF transceiver.

Richard,

Now you're talking my language...almost!

I also want to built an ultra-portable rig, except I want a PSK31-only rig that I can pack with my laptop for my travels. I know Small Wonder Labs already makes this, but this is a homebrew forum, and that's what I want to do. When building any HF rig, the frequency control systems are usually the most complex part. I'm hoping that by developing this little configurable & programmable module, I'll have a building block I can press into service for VFO's BFO's, and other heterodyne oscillator applications.

The Atmel chips are certainly good candidates for the application...low power, fast, powerful, & cheap. I know that with a PIC (and possibly the Atmel) chip, you can make a 50mhz frequency counter with as much resolution as you care to program into it, commensurate with the counting speed tradeoff. Thus, 10hz measurement resolution could be achieved with a 10 frequency corrections per second. As you pointed out, the counter could be programmed for a lower resolution, faster update mode that would be used to acquire, and then slip into the slower, higher resolution mode to maintain. A simple 8 bit R-2R D/A converter could be used for coarse tuning so that the loop doesn't have to work so hard. In a VFO with a 500khz bandspread, that would initially place the frequency within a few khz. I've built VCO's using fast CMOS unbuffered inverters that work to over 150Mhz, so that part isn't difficult.

Overall, I think all the technology is proven...someone just has to do it. My PICLite Starter Kit should arrive any day (only $36!) and I hope to get started.

>some numbers of MHz and dB attached.

? What is wrong with that?

An NE602 or SA602 is just a means to an end. It's a nice little IC
that allows some balanced mixing AND as the active device for the
local oscillator. A single IC, dual function. Used within its limitations
it is AS ACCURATE AS ANY OTHER DEVICE.

>> NO analyzer means NO results.
>>
>Of course I'd rather have that much information than no analyser at all.
>(Len, if you happen not to mention something that is completely obvious,
>I still assume that you're completely aware of it. Kindly extend the
>same courtesy to me.)

I have NO idea of what is "completely obvious" to anyone. Everyone's
mileage varies.

>But once you have a "fun" analyser giving you basic indications, it
>inevitably draws you into asking more searching questions, like "How
>much of a harmonic problem do I really have?" That's where fun analysers
>come unstuck, because you don't know how much of those indicated

>harmonics are real, and how much is being generated in the analyser
>itself.

Let's not lump all the "non-pro" analyzers into the "fun-toy" category,
okay?

Sorry, but I can quickly categorize/calibrate/check ANY analyzer as
to whether or not whatever it shows is "real" or internal. There's lots
of written information available on how to do that...and a bit of thinking
will reveal the very same thing.

>An important practical crunch point for amateurs is "Does this
>transmitter meet the FCC requirement for 60dB minimum harmonic
>suppression?" Now you discover the big difference between 60-70dB
>on-screen dynamic range, and 60-70dB *spurious-free* dynamic range. The
>first is easy - the second is damned hard to guarantee in a HB design.

Sorry, you've drifted outside of specific spectrum analyzer use. The
harmonic content of ALL transmitters can be measured WITHOUT
any spectrum analyzer, as accurately (in most cases moreso) as with
an analyzer. A spectrum analyzer is much much faster in that
application, but harmonic content measurement is not dependent on
its use.

Good operation and good specifications in homebrew designs are as
good as the designer, as good as the other equipment for calibration
and characterisation that is used. It's all together. It's only "damned
hard to guarantee" if there is nothing available to ascertain operation
and calibration. That can exist equally well for an HP 141 plug-in or
one that you term a "fun" NE602.

>If you get to that point - and many people will - then you'll wish you'd
>taken the extra trouble to build an analyser that you could trust a
>little more. The NE602 type categorically will not hack that kind of
>problem, because the equipment under test is probably much cleaner than
>it is!

Good grief! There's plenty of instances in metrology where actual
measurements are done to a higher level than what each piece of
test equipment can do. Time and frequency measurement is a good
area for examples in that, other areas' explanations will take more
time to describe than I have at the moment.

EVERY single piece of test equipment MUST be used within its
limitations. That INCLUDES your "HP 141" racks, Anritsu analyzers,
etc., and whatever else is there.

>The W7ZOI type may just do it, with care, and the same is true of
>the 141 generation. Only the best modern analysers will ace the problem
>without needing careful attention from the user.

Nonsense. Each and every "user" had damn well pay close attention
to using whatever they have within its equipment's limitations. That

holds true for the best of Rhode & Schwarz wares AND for the "fun"
SA602/NE602 analyzers.

>>>Very easily, in the same ways as you test a receiver for strong-signal
>>>handling.... but most graphically by looking at the same spectra with
>>>two analysers side-by-side. The one showing fewest signals is the one
>>>you can rely on most.
>>
>> Have you priced the used spectrum analyzers lately? Do you expect
>> others to have ready access to "another" spectrum analyzer?
>>
>That comment was mostly to make the point that the cleanest display is
>the most real.

You're going to have to explain that better..."clean" is highly subjective
and subjective judgement in any metrology effort is a no-no.

>The absolute standard of comparison is the perfect spectrum analyser
>with no spurious responses.

Okay, show me one. They must be in storage with bottles of the
"universal solvent" and other fine ideas...

>When I built the first "fun" analyser (which had to wait until the
>hardware collection had expanded to include a good oscilloscope) I found
>it quite disappointing, because it still wasn't showing me reality. I
>was still having to think "Now if I had a *good* spectrum analyser, what
>would it probably be showing me here?"

That's nice. But you are drifting towards extreme categorization of
equipment. Simple, low parts count home projects are "fun" (in your
terms, like toys or something for recreation. The only "GOOD" gear
is semi-pro, expensive, etc., etc., etc.

>Out in the workshop, the real hardware adds real-life numbers to the
>ideas, and also checks that there isn't anything happening that I hadn't
>thought of.

In MY workshop, nearly everything I do and use is pure FUN. If I use
them within their limitations, then they give me REAL numbers as
valid as anything I use from a small pro lab's $400K capital collection.

>In this particular case, there does exist a very good, reliable,
>second-level design (the W7ZOI). It's a little more expensive to build
>than the entry-level stuff, but not significantly more complex. It's
>very well designed, so while you're building it you'll learn some very
>useful things from a top amateur (and former professional) RF designer.
>It's also modular, so you can build it in stages, and upgrade various
>parts as and when you want.
>
>Bottom line: having played with the entry-level NE602 stuff myself, my
>advice would be:
>

>* If you only want a "fun" analyser, then go for it and have fun.
>
>* But if you want the analyser as a tool to help you develop good radio
>gear, go direct to the W7ZOI design.

So...bottom line is that spectrum analyzers with NE602s in them are
kiddie toys useable only for entertainment and recreation?!?

Not a good characterization, that. Used within its limitations, the
"kiddie" instrument is as accurate as anything else. Input level
displayed linearity is a direct function of the successive detection
logarithmic chip used in the back end...has very little to do with the
front end. Resolution is again a back-end concern and is a direct
function of the filtering of the final IF in the analyzer...and the sweep
rate and sweep span (all related). If you want linearity in the
horizontal as to frequency, then you have to pay a lot of attention to
VCO (or equivalent) control and that has little to do with messing
about with the front end mixer.

The front end of any spectrum analyzer is the place where your
spurious responses are generated, if any at all. If you are going for
the very best in higher-level inputs then you absolutely need a high-
IM-rated mixer, which also probably needs a high-level LO. Both of
those cost a great deal of money...and the higher input level free of
spurious responses may or may not be worth it. It may not be
worth it when one of those "fun" analyzers don't exhibit any false
signals or spurii below a specific input level.

retired (from regular hours) electronic engineer person
formerly an Associate Editor with HAM RADIO Magazine

PS: I once or twice used an HP 141. It always had "ordinary"
oscilloscope plug-ins in it to make it overall an oscilloscope. Shrug.

Regarding the device choice. I think the designers reason for using the THA15 is that he found a very inexpensive source for the device and he already had a 40w exciter in production. It was a suitably inexpensive device.

FCC approval not required if used outside the US.

We are not based in the US.

My company is a re-seller for NRG products among others.

However frequency stability, harmonic attenuation and spurious products would probably meet type approval spec in the US. Not sure how tough your EMC and or electrical safety requirements are but it would probably meet those to after looking at some of the budget end equipment that has FCC type acceptance.

I just love those Part-15 Talking House transmitters.

Does the FCC still allow self approval on certain equipment?

At one time, you could call the FCC Field Office and approach the situation
like FAA handled
non-commercial built planes. I do remember in the 1970s that the FCC would
provide this
approval from the Field Engineers. Many things changed in the 1980s - in
the
"name of progress and deregulation" - but I believe "self approval" was NOT
one of them.

Joe

I actually have (had?) a project in flight to do just that. Unfortunately, pressures on my time have prevented me from making much progress lately. Perhaps as the weather cools.

My background is as a chemical process control engineer. This seems like an obvious application of traditional process control algorithms. Even more to the point, I have a history of applying simple computers to process control problems, and this seems like a good candidate.

I spent a LOT of time working on the basic VCO. In my case, it happens I was looking for something in the 9 MHz neighborhood, to build a 20 meter rig with a 4.9 MHz IF (to take advantage of cheap crystals, of course). It turns out to be a lot harder than it sounds to come up with a reasonable stable VCO at that frequency.

In my case I wanted to be able to tune the frequency, but this is really not so different from what you want. I get the frequency by twiddling the shaft encoder, but once the frequency is gotten, I now plug it into the controller, so the second part is basically what you are talking about.

I, too, had assumed when changing frequency I may need to go to a ten times a second sample, then change to once a second after I got there, but I'm not entirely sure this is what I'll do. Given that you have a VCO and a DAC, and the VCO has a relatively fixed relationship between the control voltage and the frequency, I ought to be able to output the voltage for the desired frequency immediately, then fine tune based on the count.

Which brings up another issue ... the DAC. In my case, I wanted 70 kHz of coverage, so I needed a DAC with a fair bit of resolution. 8 bit DACs are cheap, but when you get into the 12-16 bit neighborhood they tend to not be so cheap. Also, it seems like the lion's share of serial DACs are surface mount, and you really want serial to keep the parts count down.

My initial thinking was that you might be able to get away with an 8 bit DAC given that you really only want one frequency. Assuming a 4.915 IF, you would want to build a VCO with a range of about 9.1549 to 9.1551 - seems pretty tight, although it looks like a candidate for a VXO, which could be a lot simpler problem. The challenge you have is that you can't have the frequency hopping about for more than a couple of Hz for PSK, so you really want about 1 Hz or better resolution on your DAC.

In fact, as I think about it, the VXO looks like a great candidate. Since the VXO can be quite stable, you aren't going to need to be quite so quick to respond to disturbances that want to move the frequency, so the once per second sample to allow 1Hz control isn't going to be such a big deal.

If you build the VXO such that, under "typical" conditions it is spot on with the DAC output at half scale, now you can preload the reset in your PIC controller to deliver half scale at turn on. The total drift of a VXO ought to be only a few tens of Hz anyway, so the PIC shooed drive the frequency to be spot on within 5 or 10 seconds. It's unlikely that you will be able to find a QSO in that amount of time, anyway. Of course, thermal disturbances are going to want to move the VXO a bit, but these are slow, so the PIC should have no trouble keeping them in check.

This probably doesn't really deliver to your "building block" concept, but it seems pretty straightforward for PSK. If you want a generic building block, as best I can tell you will need 1) a good, stable VCO (hard); and 2) a high-resolution DAC (expensive).

For my project, I am starting to lean toward the AD9850 as being simpler and cheaper, although I started out where you are now, feeling like it was overkill for the purpose. Still, I'd like to prove the concept of using PID control for frequency.

I agree the LO is the hardest part of a radio, especially if you want fine resolution and digital programmability.
I would be interested in your VCO circuits using inverters if you are willing to share these. What sort of phase noise performance have you got with these circuits?
I wonder if you could use a coax transmission line as the tunable element, and ground different sections of it using diodes for different bands? I would be aiming to use the LO at 4X operating freq, so it can be divided for a quadrature generating circuit. I plan to use the Tayloe circuit as a bilateral SSB RX/TX, using a quad bus switch (say the FST3253)

Richard,

Now you're talking my language...almost!

I also want to built an ultra-portable rig, except I want a PSK31-only rig that I can pack with my laptop for my travels. I know Small Wonder Labs already makes this, but this is a homebrew forum, and that's what I want to do. When building any HF rig, the frequency control systems are usually the most complex part. I'm hoping that by developing this little configurable & programmable module, I'll have a building block I can press into service for VFO's BFO's, and other heterodyne oscillator applications.

The Atmel chips are certainly good candidates for the application...low power, fast, powerful, & cheap. I know that with a PIC (and possibly the Atmel) chip, you can make a 50mhz frequency counter with as much resolution as you care to program into it, commensurate with the counting speed tradeoff. Thus, 10hz measurement resolution could be achieved with a 10 frequency corrections per second. As you pointed out, the counter could be programmed for a lower resolution, faster update mode that would be used to acquire, and then slip into the slower, higher resolution mode to maintain. A simple 8 bit R-2R D/A converter could be used for coarse tuning so that the loop doesn't have to work so hard. In a VFO with a 500khz bandspread, that would initially place the frequency within a few khz. I've built VCO's using fast CMOS unbuffered inverters that work to over 150Mhz, so that part isn't difficult.

Overall, I think all the technology is proven...someone just has to do it. My PICLite Starter Kit should arrive any day (only $36!) and I hope to get started.

If the VCO can be made to have good short-term stability (we could discuss this requirement for a long time), then there are more options for how to make the control loop. I was toying with the idea of 2 simple 8-bit D/A's, one operating a coarse tune varactor and one running a fine tune varactor. Of course the problem here is that the overall 16 bit tuning curve would not be monotonic, and could have numerous slope reversals. This might be overcome by having a 'learn' mode where the system builds something like a frequency lookup table for subsequent open-loop random access. Once you've pre-tuned to within approx 1 part in 65,000, the closed loop part could take over. As to +/- a few hertz wandering affecting the PSK31 signal, I think it's mostly a matter of how fast/slow the wander rate is. Slow, small frequency wandering will probably be tolerated by PSK-31 software's AFC function.

Richard,
Essentially, you take whatever is the latest & fastest version of a '74HCU04. (The "U" is very important...it MUST be unbuffered). You capacitively couple a varactor to the input and another to the output and drive them from the same tuning voltage. An inductor from output to input completes the circuit, where L resonates the two varactors. Using appropriate varactors, I have made HF VCO's that tune almost a 3:1 range. I have operated this circuit at over 150MHz. I don't have numbers for phase noise but it was good....not as good as a crystal of course, but pretty good. This particular VCO was used as the first LO in an HF (60MHz) spectrum analyzer. It was driven from a phase detector whose other input was a DDS. The PLL/DDS combo allowed fine tuning resolution along with wide loop bandwidth, resulting in a very good, fast tuning LO.

Joe
I agree the LO is the hardest part of a radio, especially if you want fine resolution and digital programmability.
I would be interested in your VCO circuits using inverters if you are willing to share these. What sort of phase noise performance have you got with these circuits?
I wonder if you could use a coax transmission line as the tunable element, and ground different sections of it using diodes for different bands? I would be aiming to use the LO at 4X operating freq, so it can be divided for a quadrature generating circuit. I plan to use the Tayloe circuit as a bilateral SSB RX/TX, using a quad bus switch (say the FST3253)

W3JDR <joe@roccis.com> wrote in message news:LEGTa.12005$634.10762@nwrdny03.gnilink.net...
Richard,

Now you're talking my language...almost!

I also want to built an ultra-portable rig, except I want a PSK31-only rig that I can pack with my laptop for my travels. I know Small Wonder Labs already makes this, but this is a homebrew forum, and that's what I want to do. When building any HF rig, the frequency control systems are usually the most complex part. I'm hoping that by developing this little configurable & programmable module, I'll have a building block I can press into service for VFO's BFO's, and other heterodyne oscillator applications.

The Atmel chips are certainly good candidates for the application...low power, fast, powerful, & cheap. I know that with a PIC (and possibly the Atmel) chip, you can make a 50mhz frequency counter with as much resolution as you care to program into it, commensurate with the counting speed tradeoff. Thus, 10hz measurement resolution could be achieved with a 10 frequency corrections per second. As you pointed out, the counter could be programmed for a lower resolution, faster update mode that would be used to acquire, and

then slip into the slower, higher resolution mode to maintain. A simple 8 bit R-2R D/A converter could be used for coarse tuning so that the loop doesn't have to work so hard. In a VFO with a 500khz bandspread, that would initially place the frequency within a few khz. I've built VCO's using fast CMOS unbuffered inverters that work to over 150Mhz, so that part isn't difficult.

Overall, I think all the technology is proven...someone just has to do it. My PICLite Starter Kit should arrive any day (only $36!) and I hope to get started.

Another approach is to lock an oscillator running at the output
frequency to the input. Try dividing the oscillator by two and use that signal
to compare to the input.

The AD9954 has a clock multiplier, and only needs a 20mhz clock
to drive it.

If anybody tries using one of these and makes up some circuit boards
let me know (before I try and wire mine dead bug style!)

I'm building a balanced line antenna tuner and have settled on link coupling in order to eliminate the balun from the circuit.

I have a big rotary inductor out of an old Murch 2000A and would like to use it as the output link. I've decided on a variable (tapped) input link. I'm wondering if anyone has done this and what technique they used to mount the input link (i.e., how to get it close enough for effectively coupling).

Of course, the standard answer anymore seems to be the AD985x series of DDS chips. Far Circuits has a board to build a 0-30 MHz DDS from a 9850, and by replacing the clock with a 120 MHz part, it will easily get up past 50. I think the 9854 will play up to 400 but getting a simple, inexpensive clock could be a push.

High speed prescaler chips are relatively inexpensive. One thought that occurred to me (but I haven't gotten any farther than collecting the parts) is to use something like the TR4400/4900 or TRF2050/52 then prescaling down to something sensible. Typically, you're going into a mixer anyway, so the square wave the prescaler would leave you with would be an advantage.

I believe Steve Weber was able to make the 4400 play as low as the 50 MHz region directly - you might poke him one. Although most of these chips are made for cell phones, I suspect most will work at lower frequencies. It's usually just a question of doing the math.

..

Yes the 995x has a 4 to 20 multiplyer, but this increase the jitter on the output frequnce, therefore i prefere an 400MHz precition osc. if it is possible to find it.

Best regards

Frank

One way would be to have a VCO and simple 8-pin PLL I guess clocking the chip ?

Your going to be hard pushed to find an XTAL block with a 400MHz output.

Some of the older Pentium mother boards used to use an XTAL and a chip to
generate the main hundred-odd MHz clock, not sure what the chips where though.

For that matter, Wes Hayward has his own webpage, and he has some material
related to the project at:
http://users.easystreet.com/w7zoi/SA.html
According to that page, one can download the original articles from
the ARRL website, in pdf format, but doing a search over there, I don't
get a hit on the articles.

I don't see it in the 2001 Handbook (the only recent one I have), but
perhaps it's in that new Hayward book, "Experimental Methods in RF Design"
but I've yet to order my copy.

And of course, Kanga, http://www.bright.net/~kanga/kanga
has boards for the project, and they have some additional information
on their website.

This is not a good design. The tapping in generally reserved for the output side of the tuner with the input being "relatively" fixed with only a little bit of adjustment, via a swinging link or a series capacitor. You need a wider impedance matching range on the output side, not the input side.

73s,

Evan

I got a FM broadcast band radio from the dollar store. In it it has a
16 pin SMD IC of unknown brand. Although I plan using these for my
10Ghz gunnplexers. There is one coil and a varactor diode. They use
push button up tuning and another to reset to the low end of the band.
I don't find any parts for an IF so it must be a TRF style receiver.
It has a stereo headphone jack but it's not stereo, and the headphone
cable is used for the antenna, And it runs off of 3 VDC. I'd like to
know what this chip is so I can take it down to 30Mhz.

I am looking for a source for the 12V SM FETs PD55003 and PD55008 for a QRP HF SSB amp to about 10W out
These devices from ST would seem to fit the bill quite well, but I am not sure if I can get them in retail quantities.
Anyone got any ideas re such an amp and where I can get these devices?

Thanks
Richard

626. Hi-Q RF filters, anyone?

Hi chaps,

I've decided to bite the bullet and try to build an RF filter for
40Mhz. This filter will ideally have a very, very sharp characteristic
at one single spot frequency +-20Khz and attenuate the crap out of
anything either side of this. It'll need to be tunable over a range of
say 200Khz. Can anyone give me a steer on what type of arrangement
would be best suited to fit this purpose?
Thanks,

p.

I want to increase the sensitivity of a radio control rx. To this end,
I'm going to build an RF pre-amp, which needs to be highly selective
to avoid the probablility of increased ajacent channel interference.
Hence the need for a sharp filter in conjunction with the pre-amp.

Mmm. Postscript documents. Real useful. NOT... :(

Sounds like an interesting variation on the project, but without
documentation in a standard, open format, his audience is going to be
limited.

This is a strange way of achieving your aim. You should be going for
adjacent channel selectivity in the IF, not the front end. That way
you can use a fixed frequency filter, and it can be as lossy as you
like - and it will be lossy to achieve these kinds of selectivity with
achievable unloaded Q.

If you put this filter at the RF stage where it will help with
adjacent channel selectivity,m it must be before the first amplifier,
and that will have killed your hoped-for sensitivity increase. If you
put it after that amplifier, then you may as well leave it where it
belongs - in the IF.

Radio design is always a compromise between sensitivity, selectivity
and large-signal performance. The standard topologies haven't emerged
by accident, I'm afraid.

I bought one of those recently, when they were on sale for $1.99 at
Pharmaprix (which is Shopper's Drug Mart in the rest of Canada).
I was simply curious about what was inside, and the price became
low enough that I didn't mind spending the money.

I had problems reading the IC at first. So I started out tracing
the circuit. At first, I thought/hoped it was the TDA7000, but
the pin count was wrong. I looked up that IC at the Phillips'
site (it was easier than trying to find where I'd stashed the
paper datasheet), and they made mention of similar ICs, including
two that had that tuning scheme. I went through them, and
the match was the TDA7088. Looking more carefully at the IC,

the "7088" was now visible, though it looked like it was a knockoff
or a cheap second source, rather than an IC that came from Phillips.

I'd say this is the same IC, since your "1033" could be a misread
of "7088".
Check the datasheet at
http://www.semiconductors.philips.com/pip/TDA7088.html

Likely by comparing the pinout from it with the actual circuit, you
will find a match.

I was going to post something about my findings, because they are a curiosity.
But I'm not sure where my notes are, or even where I put the circuit board.

The IC uses the same scheme as the TDA7000, ie a conversion to an IF
of about 70KHz, where an active filter can be used for selectivity.
And one of those Frequency Lock Loops which reduces the apparent deviation.
Then they throw in the circuitry for the tuning scheme.

Having once seen someone suggest using the TDA7000 as a direct conversion
receiver (when they were readily available at Radio Shack), they claimed
the mixer was double balanced, I couldn't help but think maybe these
radios would be a cheap local source for a mixer. Leave the IC on
the board, and just strip the unneeded parts of, wiring to the board
rather than wiring to that smd IC. I assume the big problem would
be that since the 7088 can't handle more than about 3V on the supply
line, it will be even worse for signal handling than the NE602 is said
to be. (And I am simply assuming it's a double balanced mixer.) But
for a couple of dollars, there are times when someone might need
a mixer that these radios can supply cheap and locally.

I've got that deja-google feeling all over again:

http://groups.google.com/groups?hl=en&lr=&ie=UTF-8&oe=UTF-8&threadm=8hl66v4l5vh8rjnp29dstmnl9neccu90is%404ax.com&rnum=6&prev=/groups%3Fq%3Dtunable%2Bfilter%2Bgroup:sci.electronics.design%26hl%3Den%26lr%3D%26ie%3DUTF-8%26oe%3DUTF-8%26scoring%3Dd%26selm%3D8hl66v4l5vh8rjnp29dstmnl9neccu90is%25404ax.com%26rnum%3D6

I like the idea of downconverting to an IF, filtering using
standard IF technology, and (if you want the output to be the same
frequency band as the input) upconverting using the same local
oscillator as the downconverter. Just change the LO frequency (maybe
use a frequency synthesizer for stability) to do tuning.

Take a look at lowband filters and duplexers from CellWave, Telewave,
etc.
Your filter is going to be a coaxial cavity about 2mx20cm with piston
for tuning.
I am sure there are some better approaches to your task :)

Vladimir Vassilevsky, Ph.D.

Thanks, Don. I'm aware this is a daft way of doing it, but I don't
have much choice. The IF stages of this rx are not accessable and no
schematic is available, either. The makers have declined to make them
available and threatened any service personel who do so with
termination of their contracts. Faced with these obstacles, I don't
see any other option, apart from boosting the tx power instead; a
solution which just brings a different load of problems.

It'll need to be a crystal filter, and your requirement that it must
be tunable means that you will convert down/up to an IF frequency and back
up/down again. (Well, you may not have to convert back up again but you
don't tell us your application).

Problem with the IF and conversion is the production of images. Images
won't be a killer problem because your tuning range is really quite narrow.

If you wanted to really cheapskate out some ceramic IF filters also seem
to meet your stated needs.

Tim.

Analog Devices will send out samples to just about anybody.
Go to their website and sign up for their monthly mailings, each

month they will send you a bingo card good for samples on up to 6 devices.
You can also request a sample of almost any part on the web site.
You might have to make up a 'bogus' company name at your home
QTH, but they don't really care. I requested a sample of the 9954 DDS,
it was mailed to me at my employers QTH. They ask you about
how many devices your company might purchase, but I just filled out
that it was for a 'future project' and 'no plans at this time'. They
didn't care and I got the sample in a week after faxing the bingo card.

AD is a VERY friendly company to get samples from.

Hello Paul,
it is time to dump that receiver and start again. It is too
small and tiddly and I know you do not like surface
mount size components. I would imagine that you
have plenty of room inside that robot of yours to
take a fairly large die cast box. My suggestion is
find a radio control receiver that you can get
circuit diagrams for or build one from scratch
on large pieces of printed circuit board using
"ugly construction" or "dead bug construction".
Google those terms and you will see what I am
talking about.

You can then build the various stages of the
receiver on separate boards and try all the
different things you have been wishing to do
but couldn't due to miniature parts, lack of access
and lack of information.
After you have a prototype ugly construction
receiver working, you can miniaturize if you
wish on the the next unit. You will need spares
anyway. Heh heh heh......it is fighting machine.

Have a look at National semiconductor application
notes for radio control receiver, they might even give
you half a dozen chips as free samples.

Google search for radio control receiver schematics.

"Buy" is a dirty word for me, but you might be able
to buy a receiver in kit form with all the information on
construction and alignment as well as a "how it works"
description.

Have Fun,
John Crighton

When the DSL gets saturated... it happens when too many people try to visit at once. It happens to me alot here at the server end of things. A T-1 line, which I am too cheap to pay for, would not really alleviate things under
such conditions. A T-3 would, though.

The VMS+Apache server keeps running, but your HTTP request is extremely delayed until your browser times out.

It's like trying to get 15 people into a telephone booth. you reach a point where no more can squeeze their way in, and the remining ones wait or begin to walk away.

Probably some leeches are sucking down the entire set of documents. It is usual in such cases and they are welcome to them. Looks quiet now.

Just try again later, it is always running. It's OpenVMS after all!

I did by the way, change the 'large' file sizes to slightly smaller size of 1500 wide, and eliminated the hard to read 'web size' files. I hope this is a good compromise. The 300DPI were just too large, (data-wise). I resampled
the original 300DPI files and resized from about 2500 wide to 1500 wide. I also re-sampled the 'thumbnail' images to a larger size to make it easier to tell what is on the page. It's not perfect but nothing is.

I have equivalent numbers of stancor, triad, chicago, and thordarson catalogs waiting. It took 3 weeks to do the UTC catalogs. I'll post notice when I get more up.

Thanks for looking!

I'm pretty sure the one I bought is being sold under the "Chateau" name. It almost seems to be a Pharmaprix house brand here for electronic stuff and accessories, and maybe they use a different name in the rest of the country where the chain is Shopper's Drug Mart.

I've noticed the same radios in the other chain drugstores, but I don't think they carry the same brand name on the package. They were selling for $2.99, but I keep seeing them on sale for $1.99.

I suspect in this sort of thing they are all using the same IC, no matter what the brand. Maybe there are other ICs intended for "two button FM" radios, but it obviously would be cheapest to stick with one common IC. I notice Radio Shack sells similar radios, but for about ten dollars and I'm not willing to pay the money just to see if the IC is the same.

How about a helical resonator. They're smaller than a cavity, maybe
not as high Q, but still higher than lumped constant tuned circuit.
They're tunable, but I'm not sure how much.

Filter at 40 MHz with 40 KHz BW means a very high Q, up to 1000.
Cavity filter at 40 MHz is big! You can try active RF tuned stage (at
40 MHz) with a positive feedback, also known as Q-multiplier. In
addition to high selectivity this will also result in a high gain,
which may overload your actual receiver. In this case you can
attenuate the signal at the output of the RF stage. You have to make
sure Q-multiplier would start to oscillate. It is an issue by itself.

I'd like to live long enough to see a helical at 40MHz that can
'attenuate the hell" out of signals outside the Fr+/-20kHz channel.

I have a HP 141 series device which is reasonable from the point of view of strong signal handling.
It is surprisingly easy to produce intermodulation effects at levels lower than you would expect.
A "forest" of signals at -20 dBm will produce IM effects by the additive effect of all their amplitudes.(you could easily get this from a 40M dipole at night for example)
In fact, my friend Rod Green has done an article for QEX on a "figure of merit" device to test receiver strong signal handling which consists of a "comb generator" with harmonics every 20 KHz, and a bandpass filter covering the band of interest - say 7.0 to 7.2 MHz. At a comb level of -20dBm most receivers will be overwhelmed.

Thanks for the suggestion, John. It *does* make a lot of sense, I must
admit. Hadn't considered that possibility, to be honest. I've never
been a fan of dead bug construction - there's no satisfaction in
seeing the finished job - so may well have a stab at using regular,
proper-sized discretes along the same lines. And yes, there's no
shortage of space, either. Way to go over the long term, I reckon.
Thanks again.

This problem was posted in 1998 to rec.radio.shortwave but no fix was reported. It surfaced again in the RADIOSHACKDX394 Yahoo group, five years later, with a posting from W1WJB and was found to be fairly commonly experienced. A simple fix has been developed and can be found at http://groups.yahoo.com/group/RADIOSHACKDX394/files/Mods/RF/MW%20%26%20LW%20Sensitivity%20Stabiliser/.
You'll need to join the group to access this folder but anyone can read the message archive. It's discussed under the thread "Sensitivity Loss Over Time".

-------Original Posting-------
From: DesertFox <craig.rommel@hamradio.org>
Subject: DX-394 Owners, Please read ->
Date: 1998/07/09

Just was something I couldn't help but notice......

DX-394 Owners, try this:

1) Set to a stronger local AM MW Station with a consistant signal strength, note reading on the LCD strength meter.

2) Either leave radio on or turn off (but leave that station tuned in)

3) In 3-4 hours (or overnight if you wish) if off, turn radio on (without pressing BAND switch) and observe LCD S-Meter.

--*in my test it was lower, from 9 to 1-3.--

4) Cycle BAND Button through SW, LW, and back to MW, and observe S-Meter reading on that same station.

--*in my observation it returned to 9--

I was able to reproduce this condition in 3 different DX-394's, base, "A", and a "B", [snip]

>I have a HP 141 series device which is reasonable from the point of view of >strong signal handling.

I'm unfamiliar with a standard that defines "reasonable." The HP-141 is basically a mini-rack with a CRT and its supply...full function is established by the plug-ins to that mini-rack. The H-P (now Agilent) part numberings for the plug-ins are (probably) 5-digit ones (I've only used full instruments arranged for a specific purpose).

I have the old TM on the military-contract purchase of HP-141s. If you need some particular information on it, I will try to help you out. I can't help anyone without knowing what the function-determining plug-ins are or do.

>It is surprisingly easy to produce intermodulation effects at levels lower >than you would expect.

That's a subjective experience statement. I know that IMs can indeed happen at "lower levels" but that cannot be pinned down to an easy or simplistic statement. Based on four decades of being rather intimately involved with receiving systems, I've learned to "expect" everything and anything. :-)

It is quite true that the front end stage of a receiver is the most likely generator of IM distortion effects, but that is definitely NOT the end of possibilities. Follow these lines by way of explanation -

All receivers are selective amplifier-demodulators. The amplifier parts are generally the IM distortion causatives due to non-linearities. If the front-end stage is made to the best possible linear operation, the stages following will experience higher and higher signal levels. At some point in some later amplifier stages, the desired and undesired signals can reach levels in the non-linear portion of those stages' operation. For that reason it is common in RF design to make a "gain budget" chart/diagram (or equivalent) to show the stage input/output levels for each level of antenna (or stimulus input) signal input. This "gain budget" information (colloquial name varies by region) can show likely places of IM distortion possibilities if the linearity of each stage has been pre-established.

The "gain budget" diagram is not rocket science stuff. If you know the gains of each stage, it's an easy task with a little calculator to scribble out stage levels at various antenna input levels. Such is most useful to examine operation with AGC on front-end and other stages. Now

that isn't a "must" in genning up one's own gizmo, but it can be a very
useful thing if you DO get some unexpected distortion of any kind.

>A "forest" of signals at -20 dBm will produce IM effects by the additive
>effect of all their amplitudes.(you could easily get this from a 40M dipole
>at night for example)

Sorry, I disagree with that sentence as written. Without knowledge of
the front-end linearity (through IP3 levels or whatever), it is impossible
to state categorically that one particular level "will produce" IM. Also,
if all those signals are "additive," then that word makes the front-end
definitely NON-linear. Truly linear amplifiers just amplify and do not
cross-modulate adjacent signals...if they did then they would be non-
linear.

I've listened to many HF bands, amateur included, at "busy" times.
The general effect of strong adjacent signals to desired weaker ones
is the familiar "splatter" of adjacent signal levels still being amplified
after being in the skirt attenuation of the final IF filter...those strong
adjacent signals still have a high enough amplitude to mess about with
the detector and demodulation process. That is NOT a true IM
problem but rather one of skirt attenuation in the final IF filter.

>In fact, my friend Rod Green has done an article for QEX on a "figure of
>merit" device to test receiver strong signal handling which consists of a
>"comb generator" with harmonics every 20 KHz, and a bandpass filter covering
>the band of interest - say 7.0 to 7.2 MHz.

Whatever is useful is always welcomed. However, a two-signal, equal-
level IM test signal is still a useful basic test for overall linearity.
While
that is most often done by signal frequencies within the final IF passband,
unequal-level testing at wider separation of frequencies can also show the
"splatter" effect in quantitative terms...i.e., having an undesired signal
in
the skirt selectivity region where attenuation may be high but is not
infinite.

>At a comb level of -20dBm most receivers will be overwhelmed.

They will? I've not been able to test "most receivers." Not even close
to that. I've fully categorized the operation of three HF receivers that
I've owned and know what they can do. Only the ancient National
NC-57 (a tube type) came close to being bothered by a 10 uW RF
input, certainly not "overwhelmed." No doubt other receivers will
vary.

Please let us know the bimonth date of your friend's article appearing
in QEX. That should be interesting.

Hello Paul,
since you are not keen on dead bug construction here
is a couple of websites that talk about Micron radio
control kits.

http://www.micronradiocontrol.fsnet.co.uk/

http://www.norcim.fsnet.co.uk/

I am sure there are other kits around, maybe someone
else will mention some.

Radio Control Models & Electronics magazine is still
around. Years ago there were lots of construction
projects. I don't know if the magazine still caters for
the do it yourself enthusiast. Decades ago it did.
http://www.hhc.co.uk/pages/show/entry_Level/5/entry_code/HCOHOBMODPUB/single_record_flag/5
9
You could enquire from them about build it
yourself radio 40 MHz radio control systems.

Here is another site with an article on interference and
servo connections and lots of other good stuff. Shows
your airtronics/(sanwa) servo connections.
http://www.uoguelph.ca/~antoon/hobby/hints.htm
No need to change servos with a different receiver.

Back to your interference problem. Is your operating
channel frequency smack in the middle of the 40 Mhz band?
If so, maybe you could try a different set of crystals, so
that you operate as far away from everyone else as

possible. Or simply just borrow a different set of crystals
in case there is a weird mix going on, just to eliminate
that possibility.

How did you go with Win's soft start motor controller?

Regards,
John Crighton

We've recently got wise to that one and I've ordered a pair of xtals
from the *last* channel of the band. That's what we'll be running with
come the last week in August, when we're due up for the next filming.

Hello Paul,
you are dragging the anchor a bit. That was months ago! :-)

Have a look here
http://www.ife.tugraz.at/datashts/nsc/h7912.pdf
Page 9. Application hints, has some good reading
on how to play around with the input transformer.

Is Henry's Radio still around? They used sell
sets of IF coils for hobbyists and experimenters. My
Henry's catalogue is a bit old. A nice Indian gent in
an electronics junk shop in Edgeware Road gave it
to me in 1973. I should come over there and get
a more up to date copy. Are the electronic disposal
shops still there?
Maybe rob some 455 KHz IF coils out of a dud
transistor radio if necessary. Save some dosh.

Get that Dalo etch resist pen out, bottle of ferric chloride
and sharpen your old soldering iron.

You have a good Tek CRO and a Signal Generator.

Do I sound like I am pushing you? Heh heh heh....

It would be interesting to have some tests done on the original
receiver. If I remember the start of the thread, the receiver
is not sensitive enough. I can't help but wonder if it's insensitive
or it's too sensitive, leading to overload in the front end.
That would be just as bad (in terms of operational range) as an insensitive
receiver.

Likewise, if one had an idea of the IF bandwidth, it would be easier
to know if the problem really needs fixing, or there is some other
issue. If the thing is using some sort of ceramic filter, looking
at the board would hopefully say what type (unless the markings have
been sanded off), and then the specs could be found. Assuming it's
a standard IF frequency, maybe one could find a narrower filter
that would drop right in. For all we know, it may have too wide
an IF, and that's causing the initial problem.

Knowing the bandwidth of the existing filter would also make it
easier to figure out a complete replacement for the receiver.
In this day and age, ceramic or crystal filters are the way to go,
not a bunch of IF transformers. Pull parts out of a cordless phone,
at least the 49MHz type, and you'll get a filter suitable for
narrow deviation FM and a crystal for converting from 10.7MHz
to 455KHz. If FM happens to be the operating mode, then pull
out the whole IF strip. If that filter is too wide, pull the
455KHz ceramic filter out of a am BCB radio, or for something
narrower, a CB set. The possibilities are endless.

Not necessarily the solution, I got bitten by that one once some 9 or 10 years ago when I used to fly radio controlled aircraft (in the UK on 35MHz). It bothered me when someone else at the flying field had the same crystal as I did and I had to wait for them to finish flying before I could fly. So bought another pair of crystals, the highest I could find, if I recall that was channel 83 (35.230MHz). Everything was fine for a while but a few weeks later I crashed after losing radio contact with my plane.

A little investigation (in between gluing the aircraft bits back together) found the cause. A channel vs frequency listing, compared with the MHz printed on the crystal case revealed that the receivers were single conversion superhets with 110KHz IF. Channel separation was 10KHz. Clearly with that setup, image rejection is practically negligible. So someone transmitting on channel 61, 220KHz away, interferes with channel 83. After that I went back to my crystals on 76 smack in the middle of everyone elses, learnt to be patient if someone was already using the channel, and had no more problems ;-)

Hello Michael,
you are correct, there are many possibilities. I would
like him to do some tests also.

The main stumbling block for Paul is no information
on the present Sanwa receiver and an understandable
reluctance to poke around and then kill it

accidentally, especially if it is borrowed or belongs
to a mate.

I suggested building a new Rx that is physically big
so that experiments and mods are easily done by
Paul. If the CRO probe slips.....no big deal. :-)

We know of this LM1872
http://www.ife.tugraz.at/datashts/nsc/h7912.pdf
that we can all look at and help out with suggestions.
Do you know of anything else we can all see on a
website?

Hello Hans,
what brand/make was that R/C set that you had?

You have reminded me of a silly incident at my model
flying club decades ago. One of the wealthier club

members was having all sorts of trouble with his model, engine and radio gear so he flung heaps of money at a ready made, ready to fly model with an expensive four stroke engine, and a new expensive all singing and dancing radio control set. First day out with the new model and everything is going well for him, he was doing stunts all over the sky.

My models were el cheapo sticks and tissue construction, I couldn't afford nice covering film/material. I was more interested in home built radio control gear. Radio assisted free flight was more my style.
When the fuel ran out in my models I didn't mind walking a few hundred yards if necessary to retrieve my model. So I am off for a long walk with my transmitter still switched on as one would. (The receiver gets switched off first then the transmitter.)

The rich guy is stunting around and decides to buzz me at low level about 20 feet above the ground.
His model flies over me and then nose dives into the ground near by. I could here his servos twitching away as I walked past the wreckage.
After I retrieved my model and switched off my transmitter, I stopped by the little gathering at the wreck site. The rich guy was operating his servos OK and scratching his head. " I spend thousands on my model and that bastard John Crighton comes here every weekend with 50 dollars worth of homebuilt junk and flies. It just isn't fair." "Moan...grumble..moan."
I didn't try to explain that his receiver got swamped. His mates put the crash down to pilot error at low level, and that was that.

Fun and games, eh! :-)
Regards,
John Crighton

Source record: 33887

I added a wireless router to my DSL modem, and I have 2 meter noise 10db over s9.

Any one else have experience with wireless routers near radio receivers? Any data base on EMI verses brand model?

I would make a guess that some models are better than others.

The 800 support line for my vendor was no help.

I have not ascertained if the EMI is coming out the units antenna, the power cord or through the case. I an going to take a look at their FCC filing data.

By the way the 2 wireless phones (digital) that I have are no problem, but I may have lucked out with the correct brand!

It was never intended for online document distribution, though.
Postscript is for (obsolete) printers, and .PS files are an (obsolete)
hack.

.PDF is designed from the ground up for online viewing, and it's less
likely to require users to compile their own viewer application. :)

Actually, neither .PS or .PDF is as nice as DjVu for onscreen viewing,
but of the three, .PDF has by far the best shot at long-term archive
survival.

674. Flat spiral coil winding

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-28 17:15:23 UTC
From: G&#65533;ry Duyck <gery@duyck-co.be>
Message-ID: <3f2559f9$0$271$ba620e4c@reader0.news.skynet.be>
Source record: 33891

I made a good deal today!
I bought 12kg (=26.5 pounds) of 0.9mm (= 20.5awg) varnished coper wire for
20 euro
(=$23 US).
Pretty cheap isn't it!

I want to wind some flat coils with it to use with my homebrew PI metal
detector.

I place 2 sheets of plexiglass above each other with a round piece of
plastic
with the thickness of my wire and the inner diameter of my coil.
Then I start winding (40 turns).

Even if I wind very carefully twe wire keeps on moving above each other,
so I don't have a neat sipral :-(It's very frustrating !

Now I just do it with one piece of plexiglass and the round piece of plastic
glued on it,
and just wind and glue it together at once.
That's working, but it takes a while before your coil is finished!

Is there any trick for winding sprial coils ?
I saw some pictures on the internet with homebrew spiral coils, but without
explanation...

Any tips or hints would be welcome.

675. mutual inductance / coupling coefficient

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-28 17:15:34 UTC
From: Active8 <mcolasono@earthlink.net.invalid>
Message-ID: <MPG.198f2443e34f2c39896f2@news.east.earthlink.net>
Source record: 33892

hi:

i'm trying to find a way to get an accurate approximation (oxymoron?) of mutual inductance between coils for different cases like tapped coil, transformers, bifiliar/trifiliar/quad ... wound transformers, etc. with different cores. so the mutual inductance can be used in analysis without having to build the coil first to measure the M.

i was looking for the Neumann double line integral and all i could come up with was

http://www.distinti.com/docs/ni.pdf

sec.6 of that doc looks promising, but i'm not sure it's the Neumann integral. it allows the separation of the centers of the coils to be changed, but it looks like that's only along the radial axis. so i don't think you can use it for coupled coils offset along the long axis, like:

---/\/\/\/---/\/---

without modifying the equation.

it's also for single loop coils, though there's an adjustment for multi turn coils.

another program i found which is said to be based on the Neumann integral doesn't allow other permeabilities and the real pisser is that it's answer for two single turn loops isn't the same as that of the other program. could be because it's for tesla coils (it'll do solenoid style windings) and outputs answers for toroid capacitance, so the whole numerical method may be diluted. i don't know.

anyone have a solution for this? i'd like a link to something on the Neuman double line integral, which i couldn't find. any other method that works is ok, also.

thanks in advance,
mike

Okay thank you, but finally I think I will use a PLL chip with a parallel interface, such as the motorola MC145152. So I'm able to control it with simple DIP-siwtches, and no I²C or computer is needed :-)

I would try to use the 2 sheets of Plexiglas you mentioned and try to find a spacer the same thickness as the wire, and try not to pull the wire to tight on the form, that might make the Plexiglas bend. Where did you find the metal detector plans that you're using?

It's tragic, John. All those marvellous old places are gone now, sad
to say. They've all been replaced by shops selling factory-made
electronic products from the far east. Mail order's the only option
these days.
:-(

John, what in your experience causes this 'servo-twitching'? I've
observed it myself at close hand many times. The last time it
happened, we cured it by isolating the die-cast box the rx was mounted
in from the chassis. I still can't figure out why this worked, as I'd
have thought grounding it *ought* to solve the problem. But in this
instance, grounding it *created* the problem and isolating it solved
it! Sometimes when I see those servos behaving like they've got a mind
of their own it almost makes me believe in the supernatural.

You'll have to forgive me here, John, as i'm battling with a duff
display on the computer I'm using at the moment and I was only able to
glimpse the data for a few seconds, but this chip doesn't seem to be
suitable for 40Mhz FM, does it? I'm sure your general solution to the
problem is an excellent one, though, if a suitable chip can be found.

While I don't have a wireless router, I do have CAT5 cable run around the house, and the 2 meter interference is horrible on some frequencies. So, it might not be the router's RF output but the data rate. Just a thought.

R/C servos are EXTREMELY sensitive to trash on the power supply leads.
Grounding the box probably coupled some trash into the ground lead to the
servo.

I don't know what you have in your system, but I'd start by investing in a
few small 250 uF (nominal) capacitors and put them directly across the servo
supply leads. Use Y-harnesses to hook them in if you don't feel like
modifying a cable.

I have the same problem with CAT5 cable, too. Did some Google+Google
newsgroup searches on it. One fix is shielded CAT5 cable. Good luck,
you won't find it at your local Home Depot. The only other suggestion
was to go wireless. And the original poster had problems with that,
too.

>John, what in your experience causes this 'servo-twitching'?
In that incident with the rich guy, he was a few hundred yards
away from his model and my transmitter, only 20 feet away. even
though it was on a different channel upset his signal. Therefore
his servos twitched and his model crashed.

> I've observed it myself at close hand many times.

Waving a transmitter with a fully extended antenna beside
the model will cause a bit of servo twitching. The signal
is too strong. That is why you see people doing close
range testing with the antenna retracted.

>The last time it
>happened, we cured it by isolating the die-cast box the rx was mounted

I would have thought that grounding the RX to the box would
be good practice also.
Not having a circuit to guide you, maybe you were grounding
a spot on the PCB that should not be grounded.

>But in this
>instance, grounding it *created* the problem and isolating it solved
>it! Sometimes when I see those servos behaving like they've got a mind
>of their own it almost makes me believe in the supernatural.

You got some good advice from John R Strohm in regards
to fitting decoupling capacitors across the servo supply leads.

I am assuming that your R/C gear is operating from its
own battery supply not the main driving motor supply.
Using the same battery for the radio and main driving
motors could cause servo twitching.

Pity there isn't one of these fighting robot clubs
here in Sydney. I would like to have a go.

Paul you will have to put some pictures up
somewhere so we can have a look.

Regards,
John Crighton
Sydney

hi again:

i managed to get similar answers out of the 2 progs. BTW, the other is MANDK at:

http://hot-streamer.com/TeslaCoils/Programs/MANDKV31.ZIP
http://hot-streamer.com/TeslaCoils/Programs/MANDKV31.PDF

they do run on my winders XP, prob NT/2k, also.

how about some real life examples i can use to test?

i would need coil dimensions/geometry, N (turns), core mat'l, measured L and M.

anyone know their homebrew coils that well?

thanks,
mike

It's not exactly symmetrical. Rectifying a sine wave produces what looks
like a sine wave with pointy lower peaks, at twice the input frequency.
A little decent filtering at 2F, and the pointy lower peaks go away.

I have heard that the power supplies in some routers
(wireless or not) are noisy. Apparently, some of them
contain "dirty" switchers, if what I heard is true.

692. Transmitter tube testing

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-29 03:26:13 UTC
From: castles <castles@yestertronics.com>

I would like to build a set up for testing transmitting tubes. I was thinking of just testing a couple of points. My power supply will have a capability of 500 volts maximum at 2 amps. I would test a triode for instance for cutoff and then I was thinking of going to the plate dissapation value. I would do this short term so that the tube would not need to have forced air cooling.

I am planning to sell some of my transmitting tubes and would like to advertise them as having passed a series of tests. What tests would be most meaningful?

Thanks for you suggestions, Don

The coil does not have to be perfectly flat to have a flat spiral
characteristic. The really easy to make one is to use an
nonconductive coil form shaped like a daisy with an odd number of
petals. You pass the wire between the petals and every turn passes
through the slots the opposite way from the previous turn. This
actually produces a lower stray capacitance coil than the perfect flat
spiral.

Hello Paul,
under Features on page 1 it says 50KHz to 72 MHz
but not FM. I forgot about that. My mistake.
OK we'll keep looking for something that suits your
FM transmitter.

Or find, beg, borrow, "buy used," or build an ordinary
AM R/C transmitter. Ten quid should get you an old
style metal cased Futaba transmitter.
A model shop gave me the circuit diagram decades
ago of an old JR brand transmitter that I bought off
them in dud condition, cheap. Keep looking. That
model shop/sanwa agency are a bit mean that is why
I said dump their product.
Stick with brands that will offer support and circuits.

There is plenty of info with that LM1872 chip,
that is what makes it attractive to use.

Have Fun,

==========
If the valves are old a Hipot test would be very important to check for 'gassing'.
A Hipot or breakdown test involves a very high voltage up to 10000 V or higher and a very low current in the few microamperes region.
Real transmitting tubes (used for amateur radio power amplifiers) operate at anode voltages somewhat higher than 500 V , usually between 2000 and 4000 V.
TV line sweep tubes often used for RF Power amps in the sub kW range usually need up to 1250 V anode voltage.

In addition to an anode voltage supply ,you need an adjustable up to - 250 V grid bias supply (a few mAs) . Your 500 V supply will be adequate for a screen supply when testing tetrodes and penthodes, be it that the max current would probably not exceed 25 mA.

It was a Futaba, I don't recall which one. Very old and battered but worked great. I've been away from aero-modelling for 9 years or so and don't know what's new now - but at that time, the latest control sets were dual conversion (avoiding that image problem) and PCM (Pulse Code Modulation) compared to the old PPM like mine (Pulse Position Modulation). It always seemed to me (perhaps somewhat subjectively) that the PCM tranceivers, which were supposed to be more reliable, were in fact more prone to interference. In the presence of interference the flyer seemed to have no control, presumably because the incoming code was scrambled and the receiver couldn't make head or tail of it. With the old fashioned PPM sets it seemed that often even if interference was causing your servos to twitch a little you still had some degree of control over it, often enough to turn it round and bring it in closer whereupon full control would return and permit a hasty landing.

Ha Ha, similar story here. I was a student at the time, had very little money. Serves that rich fellow right for flying so low near you, sounds dangerous. I used to have a Hi-Boy 4-channel trainer with 0.40 cu inch 2-stroke OS engine. When it came to me it had spent at least a decade in a damp garage and required an almost complete fuselage rebuild to clear the rot. Quite likely therefore that by the time I finally flew it, the original dimensions weren't adhered to any longer. A particular weakness seemed to be the nosewheel which was endlessly breaking up during my bad landings. Solution to that one was just to remove it and fly the thing as a taildragger.

The OS40 engine worked a treat, perhaps slightly overpowering the model: I used to be able to take off and fly vertically immediately like the jet fighters at air shows.

Had SO many crashes with that plane, and came to love it - just glued it back together every time. In the end it was probably more glue than balsa wood. A number of times I had to carry the pieces home in a plastic shopping bag. By the following Saturday it was glued back together and generally caused jaws at the flying field to drop. No-one could believe anything with that much glue in it and such bad aerodynamics could actually fly. The wings (balsa sheet covering polystyrene) had snapped 4 times and been repaired by application of a fibre-glass bandage, adding significant weight of course. It actually flew quite well too, all the aerobatics no problem and I particularly used to like slow low level inverted fly bys at 10 ft or less.

Happy days ;-)

Postscript *IS* a standard, open format - perhaps moreso than most.
Try ghostscript as a freeware implementation for viewing and/or
printing the documents.

From RFC 1925: "(3) With sufficient thrust, pigs fly just fine. However,
this is not necessarily a good idea. It is hard to be sure where they are
going to land, and it could be dangerous sitting under them as they fly
overhead."

The other day, I was wondering if this was an AM or FM system.
Options may be better with an FM scheme. Though I wonder how
FM impacts on resistance to interference in this application.
The capture effect means that someone else on the frequency,
just barely stronger, will take command of the frequency. Could
that be some of the original issue? Of course, the capture
effect might also be a positive thing. Also, FM is likely to
use a wider bandwidth IF, which perhaps is a problem with
adjacent channels; I don't know about the particular band
to know how close the channels are etc.

One can pull a whole narrow deviation FM receiver out of a number
of consumer items. Those 49MHz superhet walkie talkies have them
(they seem to be disappearing here in North America, as FRS takes
over), and a bit of retuning and a new crystal would provide a
decent receiver.

As I've mentioned before, cordless phones, at least older types,
work at 49MHz and FM. The layout is likely too much trouble to
extract completely, but certainly the IF strip and IF filter
would be useful.

Many of these are double conversion receivers, 10.7MHz and
then 455KHz. The ones I've scrapped use common Motorola FM

IF strips, like the MC3359, which takes 10.7MHz, converts to 455KHz, and then the IF strip and detector. So the front end is discrete components. Note that some of such equipment uses these IC in single conversion schemes, running the internal mixer at 49MHz, and then down to 455KHz.

Motorola of course came out with double conversion receiver FM ICs, but I've yet to see those in consumer equipment.

> How about a helical resonator. They're smaller than a cavity, maybe
> not as high Q, but still higher than lumped constant tuned circuit.

I think that's a popular misconception. The resonator Q is
essentially the same as the Q of the same part used as a shielded
inductor, and the shield actually lowers the Q from what it is with an
inductor in free air (so long as it's not large enough to radiate
significantly).

> They're tunable, but I'm not sure how much.

They're certainly easily tunable over a few percent, if you need
that...

But the problem as originally stated implies a filter of fairly high
order and low in-band attenuation, which in turn implies resonators of
very high unloaded Q. 20kHz bandwidth at 40MHz in a single tank is a
loaded Q of 2000, and to keep attenuation low, the unloaded resonator
Q should be perhaps 5 times that much. It would be worse for a
multi-pole filter. All this tells me it's silly to even think of an
LC filter. Add to that the extreme difficulty of getting a set of
resonators to tune together. (To get Qu=10000 in a coaxial resonator
at 40MHz would take an air-dielectric line nearly half a meter in
diameter! Just plain silly.)

I'd opt for a front end with very high dynamic range (esp. low
third-order intermod products), into a good IF filter, etc., and a
communications protocol that optimized whatever performance measure I
needed. Talk to the people who build RF communications sytems that go
on aircraft carriers. Or talk with hams who design receivers with
third order intercepts up in the +50dBm region and higher. By the
way, you may do well by putting an ATTENUATOR on the front end, if
interference (distortion products), and not desired-signal-strength,
is the problem. Distortion products will go down faster than the
inserted attenuation.

Cheers,
Tom

> to min 50-60dB.
> Is there any other ideas to realise this.

I think the doubler may be the easiest way to do it. Because your output frequency range is so limited, it should not be difficult to build a bandpass filter for that range, perhaps even with "zeros" on the input and on 3*input. Even without the zeros, a simple 5-resonator 0.1dB ripple Chebychev design from RFSim99 shows 30dB atten at 300MHz, and that's the worst-case 1*input, 3*input atten. Admittedly, you won't achieve quite that much in a practical implementation, but should be close. (Quick playing with a zero at 300MHz makes me think a 3-resonator filter with that added zero might be enough.) Add that to the rejection of 3rd you should already be seeing (30dB min according to MiniCkts) and that should do the trick for you. Also, you can "trim" a doubler to have high rejection of the third, and low feedthrough of the fundamental, if you want.

You may also find some interesting ideas on the Wenzel web sites: specifically at http://www.wenzel.com/pdffiles/diodedbl.pdf, but you may find other things under the RF Circuits section of http://www.techlib.com/electronics/index.html.

Cheers,
Tom

I am not sure if this is the right place to be posting this, but i figure its worth a shot. OK, first of all i have been away from radio for a few years (regretably) my call is KB2YFH. Anyway, i got my ticket when i was 16 i think or maybe younger... My question is i am getting older and still have nothing but a H.S diploma and dead-end jobs to show for... so, obviously i would like to continue my education. I realize now that my only true love was fixing and tinkering with my old radio equipment. I would like to know if someone could tell me what career path i should take that will qualify me and give me the experience i need in working with electronic equipment... preferably Wireless communications, RF circuts ... you know all the skills used to diagnose and repair such things as amateur transievers etc. I was licensed in NJ, but recently moved to Florida's Space Coast (Melbourne) where i am happy to see that ham radio is alive and thriving. I assume taking courses in electronic engineering would be in the right direction, but i am not sure exactly what i should do. If anyone could please give me some advice on what type of schooling i should look for, and if possible what schools are good for what i am looking for it would be greatly aprreciated. Thank you and i look forward to getting back on the air ASAP.

You folks are talking about two different but related receivers.

The whole thing started with a 1957 QST article titled "What's Wrong
With Our Present Receivers?" which showed the weaknesses of the
multiconversion designs of those days, and how they could be overcome
by the use of recently announced packaged high frequency crystal
filters. That article described a 2215 kHz IF strip and rear end to
demonstrate the principles. The IF was chosen because a National
NC-300 receiver was avaliable for use as a front end, and the '300
used a first IF of 2215 kHz.

In QST for May, 1965, W1DX (By Goodman) described a 7 tube receiver
called the "Miser's Dream". This double-conversion rx was based upon a
pair of 2215 kHz packaged xtal filters from Hycon Eastern - later
versions of the filters used in the "What's Wrong" IF strip. Similar
filters were also made by Blackhawk. These filters were $44 each in
1959, and the receiver used two of them, one for CW (250 Hz) and one
for SSB (2.7 kHz?). It used the famous Eddystone 898 sliderule dial,
RF Q-multiplication, audio-derived hang-AGC, S-meter and plug-in coils
a la the HBR receivers. It is pictured on the cover of that QST issue.
The article does not give complete construction data - it shows a
block diagram, and partial schematic. It's more of an idea article
rather than something you'd want to duplicate wire-for-wire. Lots of
good solid rx design philosophy presented in clear readable terms that
is well worth reading today.

While the Miser's dream was relatively simple, it was obviously not inexpensive to build, considering that many of the key parts were expensive and almost certainly had to be bought new. The dial, tuning capacitor and filters alone would cost about $120 in the mid-1960s.

The 1967 ARRL Radio Amateur's Handbook features the "Junior Miser's Dream" (JMD) receiver. This is a single-conversion 5 tube rx that is obviously derived from the 1965 article, meant for easier duplication and lower total cost. The "JMD" rx uses a two-speed Miller planetary-drive dial that was popular and relatively inexpensive at the time, RF Q-multiplication, bandswitching, and Miller slug-tuned coils in the front end. Selectivity is from a two-crystal filter at 3300 kHz. I recall that the JMD did not include AGC or an S-meter. The article points out that the Miller coils used in the front end are an important part of the performance and that substitutes should not be used.

Both receivers used built-in solidstate power supplies, a single-ended 7360 first mixer and no RF stage. Both were relatively simple compared to many of the multiconversion multibottle designs of the time. Both suffer from relatively poor image rejection and drift on the higher bands. The former is due to too few tuned circuits ahead of the first mixer, and the latter to the instability inherent in a simple tunable LO operating at relatively high frequencies. The main problem with duplication today is finding the parts.

--

For about a dozen years or so I owned a small 7 tube receiver that was obviously based on the Miser's Dream. I bought it at a hamfest in the early '80s and sold it to another ham some years back. I don't know who built it or when, but the construction quality/craftsmanship was excellent. I built a small power supply for it, which was also sold. This little receiver uses an uncalibrated National dial, IF in the ~1500 kHz range, and covers 80 and 40 meters by means of band imaging. Instead of an RF Q multiplier it uses a dual tuned input circuit. No S meter but it had the audio-derived hang AGC.

Schematics of the little receiver and power supply may be seen at:

http://www.qsl.net/ab0cw/littlereceiver1.jpg

http://www.qsl.net/ab0cw/littlereceiver2.jpg

http://www.qsl.net/ab0cw/littlereceiver3.jpg

And a picture of the receiver itself:

http://www.qsl.net/ab0cw/littlereceiver.jpg

The wood cabinbet was added by the ham who bought it from me.

Between those schematics and the QST article it should not be too difficult to recreate a schematic of the Miser's Dream. Coil data would have to be derived all over again.

--

My suggestion for a "2003 Miser's Dream" would combine features of all three receivers, and be based on available parts. I'd dispense with the RF Q multiplier and use a double-tuned input circuit with either big air-core coils or toroids. Depending on the crystal filters available, either a band-imaging design or a multiband premixer-LO system would be used. The 7360 beam-deflection first mixer could be replaced with a 6JH8, or perhaps a 6ES8 in the classic Pullen circuit. A variable capacitor with integral dial drive from a junked BC-221 frequency meter or ARC-5 transmitter would not only reduce cost but also do a better job. Power supply would be external for size, heat and weight reasons.

If your main interest is in diagnosis and repair, I suggest you look into an Electronic Engineering Technology (EET) curriculum. Courses and degrees are offered by a lot of community colleges, as well as technical schools. Visit your local community college and have a talk with a counselor there -- he or she can give you a lot more information about what they offer, what the course content is like, and the kinds of jobs it'll prepare you for.

An Electrical Engineering (EE) degree at a college or university prepares you more to do design, rather than repair. A BSEE (Batchelor of Science in Electrical Engineering) curriculum involves a lot more mathematics than an ASEET (Associate of Science in Electronic Engineering Technology) or BSEET degree. If you follow a traditional order of course work, you'll be in a BSEE program quite a while before you get to much that you recognize as electronics, since you'll usually start with calculus, physics, chemistry, and, yes, English. This is to lay the ground work for you to be able to understand electronics at the necessary level when it's introduced later in the program. In contrast, EET courses are a lot more hands-on, and get to the basic subject matter earlier. But it doesn't cover the material in as much depth as in an EE program.

While community colleges seldom or never grant a BSEE degree, they generally offer quite a number of courses that can be transferred to a full college or university toward a BSEE degree, if that's your choice. Those courses are likely to be non-electronics courses, though, like the physics, chemistry, math, and English I mentioned.

You might start along one path and decide later on the other. That's fine, although you should be aware that quite a number of courses in one program might not directly transfer for credit into the other. The counselor can give you the straight story about all that.

> A little decent filtering at 2F, and the pointy lower peaks go away.

Well, actually the whole output wave is at 2* the input, which is I
believe what the OP wanted: a freq doubler. Note that rectifying a
sinewave is the same as multiplying by a square wave of the same
frequency which is +1 when the sine is positive and -1 when it's
negative. You can use trig identities and the fact that the square
wave is its fundamental and all odd harmonics to convince yourself
that the "ideal" full wave rectifier puts out DC, 2*fin, 4*fin, 6*fin,
... -- just the even harmonics and no odds. It's only because the
rectification is imperfect that the fundamental or odd harmonics get
through. The pointy lower peaks must represent higher order even
harmonics of the input frequency.

Cheers,
Tom

Hi John,

I've already got an AM tx and rx set-up, but am loathed to use it due
to the much increased risk of interference from the speed controllers,
motors, etc., which as you will know, is far more likely with an AM
system. Keep thinking!

Oh, right. I'd assumed it was simply because at close range it wasn't
necessary. Bugger. So I've got swamping to worry about as well, eh?
:-(

>I would have thought that grounding the RX to the box would
>be good practice also.

Dunno. I'd have thought at 40Mhz and with a matchbox-sized rx, any
ground point would be the same as the next. :-/

>You got some good advice from John R Strohm in regards
>to fitting decoupling capacitors across the servo supply leads.

That rather interesting piece of advice has already been carefully
noted, John! I'd assumed that sticking ferrrite rings over all the
supply leads would suffice, but I guess you can never take too many
precautions!

>I am assuming that your R/C gear is operating from its
>own battery supply not the main driving motor supply.
>Using the same battery for the radio and main driving
>motors could cause servo twitching.

I'm afraid we *are* running the r/c stuff from the main batteries. The
reason for this is that on prior ocassions, we were stuffed by the
on-board ni-cads going hi-Z as they are prone to do, AIUI. Not only
that, but there's the blasted memory effect and their questionable
capacity even when in peak condition. Hence we run from the main batts
via a stabilised dropper well-decoupled and plenty of ferrites to
boot.

>Pity there isn't one of these fighting robot clubs
>here in Sydney. I would like to have a go.

I'd be surprised if there were not. I know a lot of Aussies are very
keen on the 'sport' and RW certainly goes out in Oz., although I don't

know on which channel, I'm afraid. In fact it goes out in about 26 countries world-wide, including the USA, Canada, China, India, South Africa and so on....

>Paul you will have to put some pictures up
>somewhere so we can have a look.

I haven't forgotten, John. I just haven't sorted out the web space yet and when I do, I'll wager the blasted FTP S/ware goes tits-up as per usual! :-(

I like John P's suggestion of a form with radial spokes, like a wagon wheel or like petals of a flat flower. You can make one from wood, with a wooden disk in the middle, drilled to accept dowels (round pieces of wood).

If you wish to make the coil as you have described, then while you are winding, use some backing pieces on the outside of the plastic. I would use maybe 2cm thick plywood. That will keep the plastic from bending while you are winding. You can put a drop of glue on outside turn of the finished coil, and it should then hold its shape as you remove the backing plates. If you wanted to get very fancy, you could add a very thin "washer" around just the outside maybe 0,5cm of the circular plastic, between the plastic and the backing plate on each side. That would make it a little "springy" and hold everything tight. But be sure that "washer" is maybe 0,1 times the wire diameter so as you fill up the coil former it won't let the middle slip.

Hope these thoughts are useful!

Cheers,
Tom

This type of coil was/is popular with crystal-radio and other AM-radio buffs... it's called a "spider web" coil. Use an odd number of spokes/petals, so that alternate turns on the wire spiral go onto opposite sides of any given petal.

I gather that one attraction to this winding style is that it results in a very low amount of parasitic capacitance, and thus a high Q.

Hello Paul,
I would try out your old AM set for sure. You never know
your luck. If the servo connections are compatible it will
only take a short time. What brand/model?

I agree with you that the AM set has an increased risk
of interference from your own motors but you said some
time ago that your robot works fine at your place but at
the venue with other competitors and their transmitters
around, the interference is bad for you with your present
Sanwa FM set.

Even if you do not fit the AM set to the robot, take the
working AM set in a box to the venue and see if the
servos misbehave in that electrical noisy environment.

Regards,
John Crighton.

<http://www.rfcafe.com/references/electrical/periodic_series.htm> has
a nice exposition of Fourier series for various waveforms, including
half- and full-wave rectified sine waves. The Rubber Bible math table
book used to have the waveforms and Fourier series for them, too.

I first got interested in them when I was about 11, in 1957. Somewhat
later I took the math class where we derived them. It was sort of
interesting to see my childhood friends constructed on a blackboard.

++++ I recently built a transmitter tube tester. I made several
sockets ,4 pin 5 pin 6 pin etc for 811, 4-400/3-500, 813, etc.For
instance,to test 811 tubes, I would drop in the 4 pin socket,hook up
proper filament,set bias voltage as per tube data, set up for 811
tubes and test all I had .. I used about 1400 Volts on plate,had
adjustable filament voltage..I had var bias,var screen.. I tested for
emission by reading plate current..I worked out very well for matching
emission on several tubes ..I also applied RF drive ,usually at 14
mhz.using a standard ham transmitter..an old Heathkit is OK..anything
with adjustable RF power out.a soft tube will come up to about normal
and will then start to fall-off..A person could keep on hand a known
good tube for comparsion...good luck Harold W4PQW Ps: I sold my
tester after I finished testing all my tubes..

However this doesn't stop you from taking a more hands on electronics
course each year or each half year. Usually you will get a little leeway
in what order you need to take classes.

Another route to go is a trade school. A friend went to ITT and loved the
instruction method there. 2-3 hours of theory followed by 3 hours of
application. He now works for Altera on there Nios Development. System.

I was going to go to my local community college this coming fall but with
budget cuts they dropped over 100 courses which all seem to have come from
their Physics and Engineering departments. There isn't a single
"Electronics"
course offered.

Amen on the grammar comment. I often look at resumes for computer programming positions. Good programmers are notoriously meticulous about things like spelling, grammar and punctuation. It sort of goes with the territory. So, if I see sloppy, disorganized language, I figure I'm not dealing with a Real Hacker. A big red flag for me is misspelled or miscapitalized names of industry brands, names or terms, such as C, UNIX, uC, kHz, etc., especially if the applicant claims to have experience in those areas.

To address the poster's original question, all of the advice I've seen in the responses is good. What I'd add from my own experience is:

1. Don't hesitate to cite nonprofessional experience if it applies. I've designed and built some nifty projects and published a few on the web and elsewhere. I put those in a section of my resume labeled "hobby achievements".

2. I have the utmost respect for schooling and degrees but I am self-taught and so are some of my coworkers. Small companies tend to focus more on results and less on credenitals, so if you're in a position where you have more abilities than you can prove on paper, you might want to try small companies.

3. If you don't get a job you wanted, ask that employer specifically what education you should pursue, and if you really want the job, come back in a year or so and try again. That makes a tremendous impression and I've been in on at least one such hiring.

4. Whatever education you pursue, do lots of hands-on projects on your own. They're fun, but they're also an important part of your education. It's one thing to write "10 watts" as the answer to a textbook problem on power supplies and another thing altogether to put your finger on a resistor that is dissipating 10 watts, or to observe how quickly a battery runs down under that kind of load.

Good luck to the original poster or anyone else who is interested in electronics. It's fun and exciting stuff!

David

It's a Futaba and it *has* been tried. We used it last time out solely
for weapon actuation and the result was *outrageously* dangerous and
uncontrolable. Far, far worse than FM. You wouldn't have believed it
if you hadn't seen it for yourself. It was pure luck that no one was
killed or seriously injured.

732. Trap test trauma

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-30 23:23:08 UTC
From: Dutchman <h@ns.co.za>
Message-ID: <3f28537e$0$235@hades.is.co.za>
Source record: 33749

Hi all,

I need some advice (moral support?) as to the correct interpretation of an MFJ259B output when testing traps as its handbook gives no guidance for trap testing. Intuitive interpretation leads one up the garden path? A commercial and home-brew trap gave the same results. Tests were done as
follows:
(All measurements were verified by an additional external freq. counter)

A 50 ohm carbon resistor was used in series with the hot output which connected to a 2-turn 55mm dia loop of wire that was loosely coupled to a
trap for 40m; the other end of the loop going back to the MFJ ground.
The total loop alone measures R=51 X=14.
Tuning the frequency with the trap in-situ resulted in 3 points of interest:

a) 7.00 MHz R=51 X=0
b) 7,08 MHz R=60 X=14
c) 7,20 MHz R=120 X=42

Which is the actual parallel resonance of the trap? My guess is point (b)
where no reactance is added or subtracted by the "load" and the trap is not
seen by the MFJ.
This is an in-between point that has no sharp tuning like points (a) and (c)

I also assume point (a) is where the loop and trap combination present a pure high dynamic impedance to the MFJ output.

The same test with a dip-meter and its associated coil only showed a dip at point a) which I consider close but incorrect. The trap is admittedly series-resonant and absorbs maximum power from the dip-meter but I contend
that testing open-ended traps may be deceptive as they seem to exhibit both
a series and parallel resonance not far apart.

Terminating the open end eliminates point (c) altogether as I proved with a
swept measurement using an IFR analyzer: There is only a minimum response
visible on the scope display around 7,20 MHz (c) which must be a

parallel
resonance as the trap is in series with the IFR input. However, the
proximity
of the trap body to the faceplate could influence the frequency but NOT
the
fact that the series resonance has totally disappeared.

Any comments will be welcome!
Thanks
Hans ZS6KR

733. Re: PIC Frequency Locked Loop

From: Murray Greenman <murrayg@edml.co.nz>
Message-ID: <3f2855fc$1@news.iconz.co.nz>
Source record: 33750

This has been an interesting discussion and some good ideas have arisen. I thought I might add my 2c into the pot.

I have been working in a related area, PLL of precision references using a micro. As well as references for 5 and 10MHz, I have a simple transmitter for 80/40/30m that uses a VCXO and phase locks it to an external precision reference, such as a GPS or TV sync. I use 50 or 100Hz as the loop frequency, and achieve stability of 2 parts in 10^7 with no real trouble, even with a room temp cheap crystal, and incredibly low phase noise and low sidebands (the 50Hz sidebands about 50dB down and the carrier phase noise is -30dB only 0.1Hz out from the carrier).

Sure, lockup time is very slow, which isn't important in this application, but you guys might like to consider some of my ideas on the subject:

* My VCXO is actually the micro's crystal. I use an ATMEL 2313, and use the 16 bit timer as the main divider. This is where you plug in the frequency you want - for example, for 3.8MHz you divide by 3800, as the counter reloads at 1kHz (actually, any multiple of 50Hz or 100Hz would do).

* The PLL operates by undersampling the counter at 50 or 100Hz. This adds gain to the loop, since 10 or 20 times the phase shift occurs, but it does mean there's an ambiguity in frequency every 50 or 100Hz. You might have to rethink that. You could count right down to 100Hz with a VCXO as high as 6.5MHz (limited by the size of the counter, not the micro speed). To go higher, use a divider ahead of the micro. The 2313 micro will run at 16MHz easily, so 20m is no problem.

* I use a simple 8 bit software driven PWM D-A converter. It can easily be extended to more than 8 bit, but the more bits, the slower it gets, so becomes harder to get rid of the PWM sample clock. I run it at 1kHz, 8 bit, which you would expect to give a strong 1000/256 = 3.9 Hz component, but I get around that through "PWM randomization" - instead of incrementing the PWM counter by one, I increment it by 13, which randomizes the output and increases the effective PWM clock to about 40Hz. BTW, this technique also works with hardware (R-2R) D-A converters, so can be used to extend 8 bit to 10 or 12 bit easily. 12 bit would need only 4 bit PWM.

* I keep the hardware gain (i.e. the voltage to frequency conversion of the varicap) as LOW AS POSSIBLE and control the system gain in the firmware. I also have filters in the firmware and techniques to remove dud phase measurements which can happen when using a TV frame frequency reference.

* I use the UART to control the device, and also to get telemetry back, for example the PWM loop voltage. The whole system operates in a 1kHz timer interrupt, so the main processor can do other things (in my case it runs a

beacon, a real time clock, and sends telemetry).

* My transmitter circuit has only 3 chips. The micro, a 74HC00 that acts as the 40mW transmitter, and a sync separator for the TV timing reference.

I think some of these things would have application in a 20m PSK receiver. The tuning range required is small, would suit a VCXO, and there's no reason why you couldn't step the frequency in 100Hz or 50Hz steps. Use a 1MHz reference crystal divided to 100Hz to lock the VCXO. You'd just need to up the settling speed by perhaps using a hardware D-A. You could change the divider by commands from the UART.
Keep the discussion going! Very interesting!

Hi Harold,

Thanks for the input on the tube testing. I have an HP-6035 Power Supply for the plate source and it
only goes up to 500 Volts. I was hoping to build something that I could just breadboard and then take
apart after I had tested the tubes. So it would be very simple and I would triode connect tubes with
more elements. I thought that this would be better than just selling the tubes with no information on
them. Mainly an emission check. Another response suggested a hi-pot test for gas. Did you find any of
your tubes to be gassy?

Thanks again for your help, Don W6QEY

I'm taking Electronics Engineering Technician at Saint Lawrence College this fall so I can pursue a similar career. It's a 2 year program, and it seems to be available at most college's. The starting salary for a technician is supposed to be about $35,000 CDN. The technologist level (3 year program) is about $45,000 CDN starting. If you wanted to go university level it's 4 years plus and the salary is much higher, but the math level is crazy.

736. Remote Control signals over coax.

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-31 00:01:06 UTC
From: Joel <joel@cyberbest.com>
Message-ID: <s%YVa.1754$P%1.659440850@twister2.starband.net>
Source record: 33752

I have a DSS receiver that I run into a modulator and then can use the Satellite all over the house as if it was cable. The problem is we need to extend the IR from the remote control. We are now using some RF units from RCA and while they worked well for a few years, over time they are drifting off frequency. It seems to me it would make more sense to build some sort of 'device' to send the IR signals over the coax and then pull it out at the receiver end. Anyone have any suggestion or experience with building such an animal?

Joel,
There are a number of products on the market that do everything you want.
They wirelessly rebroadcast the output of your set top box to other TV's,
and also wirelessly send back the signals from the remote. I can't remember
brand names off-hand, but do a search on "video sender" and you should get
some good hits.

Thanks for the suggestion, but I already have a modulator that sends the locals and the Satellite to all the TV's in the house. I just need to somehow get the inferred remote control signal back to the receiver. Considering I already have coax run to each TV, it would make sense to us that, piggy backed on the cable. I did a google search and found about what I need if I wanted to buy all the equipment.. Except I would rather build my own. Seems to me I could modulate a low frequency carrier or DC signal and send it back over the coax.

Joel,
Any RF signal you put onto the coax could be severely attenuated by any splitters that are in your distrubution network. Attenuation will range from a paltry 3.5 dB from splitter output-to-input, but could be as much as 40dB from output-to-output If you start out with a relatively strong transmitted signal and have a relatively sensitive receiver, I suppose it would work, but beware of higher than expected path losses. DC is probably out of the question because many splitters and other equipment present a DC short-circuit. You should consider a frequency of at least a few Mhz.

OK, I've been out of ham radio for a lot of years. What *IS* a voice keyer?

Is this a solid-state voice recorder/player, that lets you can certain
phrases the way a CW memory keyer lets you can CW fragments, to make it
easier to do contesting, or is there more to it?

Inquiring minds want to know...

At this point in my life I would attempt to dissuade ANYONE from attempting
to build a career from technology of any sort, unless it is totally in that
person's blood. I am talking dedication far in excess one would normally
give a spouse.

Reasons:

1. There are now very heavy market forces toward globalization. This means
most technology jobs at the low and medium ends of the scale are being outsourced
to third-world countries such as India, Mexico, and China.

2. There is rampant age discrimination in the field, and companies
make it extremely expensive to prove such. Your chances of getting and keeping an
engineering, software, or electronics job diminish greatly upon reaching the
age of about 35. Your chances of such upon the age of 40 are such that a
great amount of luck is called for.

3. Engineers and other "techies" have now become such a commodity that at
many large companies treat them with a fair degree of contempt. Basically,
Dilbert is more true to life than you might think.

4. Craftsmanship is no longer a guarantee of immortality. Whatever dedication
you place into your work will largely wind up in a landfill eventually.

Yes, this all sounds bleak. But this is life.

In your point in life, I would recommend working your way through an
accelerated liberal arts degree at a community college where you could
possibly obtain some credits for life experience. Take practical
courses: accounting, computer programming, 4 units of a foreign
language, and how to teach English as a second language. Take some
arts: pottery is generaly easy. Take math up to integral calculus.
Then fill your mind with civics, western history, and culture.

At that point you should be prepared to teach English in the Peoples' Republic of China.

Good luck,

The Eternal Squire

What happens if you try this? No link coupling - direct
impedance reading. Wouldn't resonance be at lowest Z on
the MFJ readout?

Sage advice, I fear. Not long ago there were some EE's on a usenet group lamenting the shipping of so much engineering work offshore to places like India and the Middle East. Even Microsoft is doing it, so I read. I wonder who they plan to sell all their products to with all the unemployment they generate?

Not a good time to become a techie, indeed, even in computing, as they're importing computer engineers under a special visa plan, to work at reduced rates. Nice.

Some years ago when my son in law was in engineering school deciding on a major, my daughter suggested transportation engineering, as there seems to be no end to the growth in that field. Turns out to be one of the areas where it is difficult to ship the work out of country, too. You can't build a highway in Texas by doing the engineering overseas, it's largely got to be done on site!
He's doing quite well in that field.

>--

Hello Paul,
I think you are missing my point when you said,
"We won't be using that set-up ever again for this application!"

My point is this. If the radio control set works OK, while just
sitting in its own cardboard box , at the noisy Venue, meaning,
the servos work nice and smooth. If you then install that same
Rx and servo set into your metal box robot and the servos
play up, that is now an " installation problem."
You cannot blame the gear.

Let's try and sort this out with some basic checks.

Using a field strength meter (which is just a simple
crystal set with a large moving coil meter as discussed
months ago, I assume you have made one already), are
both the Sanwa and Futaba transmitters producing
similar output power when compared to a known
good working transmitter? Yes or No?

At your place, are range checks of both the Sanwa
and Futaba R/C sets, on there own, not installed
in anything, over 100 yards . Yes or No?

At your place, are range checks of both the Sanwa and
Futaba R/C sets installed in the robot or metal test box
with "no" drive motors connected still over 100 yards.
Yes or No?

At your place, are range checks of both Sanwa and
Futaba with drive motors being controlled and
running nicely, still over 100 yards. Yes or No?

At the noisy Venue, while doing a range check of less than
30 yards with all other competitors absent or their

transmitters switched off in the Tx compound, do both
your Sanwa and Futaba R/C sets play up?
Yes or no?

At The Venue, do other competitor's radio control
sets play up like yours Yes or No?

At the Venue have you scanned the band with a
simple crystal set type radio or fancy scanner for some
bastard with a transmitter who is determined to give
you, personally, a hard time?

One last thought, I take it that you have sorted your
aerial out so that you do not have a long dangly
piece of wire as an antenna lead-in, inside the
metal robot body from the base of your whip antenna
mounting bracket to the Rx input.
If you do have a long wire lead-in, that is bad as it
will pick up local motor noise very nicely.
If your Rx is a long way away from your antenna base,
use coax for the lead-in as explained here.
http://homepages.which.net/~paul.hills/Radio/Radio.html

If after all that basic stuff has been checked and still no joy
then consider a dual conversion superhet Rx. like this one.
http://www.norcim.fsnet.co.uk/Index.htm#U
You could scratch build from the given circuit and the
description of how it works on that web site.
Or buy the kit from Micron for 32 quid.

If you are still having problems after all that,
sorry Paul, I give up.

Regards,
John Crighton
Sydney

Dutchman wrote:

Hi all,

I need some advice (moral support?) as to the correct interpretation
of an MFJ259B output when testing traps as its handbook gives no
guidance for trap testing. Intuitive interpretation leads one up the
garden path?
A commercial and home-brew trap gave the same results. Tests were done
as follows:
(All measurements were verified by another external freq. counter)

A 50 ohm carbon resistor was used in series with the hot output which
connected to a 2-turn 55mm dia loop of wire that was loosely coupled
to a trap for 40m; the other end of the loop going back to the MFJ
ground. The total loop alone measures R=51 X=14.
Tuning the frequency with the trap in-situ resulted in 3 points of
interest:

a) 7.00 MHz R=51 X=0
b) 7,08 MHz R=60 X=14
c) 7,20 MHz R=120 X=42

Which is the actual parallel resonance of the trap?
My guess is point(b) where no reactance is added or subtracted by the
"load" and the trap is not seen by the MFJ.
This is an in-between point that with no sharp tuning like points a)or
c)

I also assume point (a) is where the loop and trap combination present a
pure high dynamic impedance to the MFJ output.

The same test with a dip-meter and its associated coil only showed a dip
at point a) which I consider close but incorrect. The trap is admittedly
series-resonant and absorbs maximum power from the dip-meter but I
contend that testing open-ended traps may be deceptive as they seem to
exhibit both a series and parallel resonance not far apart.

Terminating the open end eliminates point (c) altogether as I proved
with a swept measurement using an IFR analyzer: There is only a minimum
response visible on the scope display around 7,20 MHz (c) which must be
a parallel resonance as the trap is in series with the IFR input.
However, the proximity of the trap body to the faceplate could influence
the frequency but NOT the fact that the series resonance has totally

disappeared.

Any comments will be welcome!
Thanks
Hans ZS6KR

| What happens if you try this? No link coupling - direct
| impedance reading. Wouldn't resonance be at lowest Z on
| the MFJ readout?
|
| MFJ---Trap---50ohms----+
| S0- |
| 239--------------------+

Thanks for your suggestion but this also gives the same as the terminated measurement where the only only throughput occurs way off parallel resonance both sides but using the MFJ the actual parallel resonance point cannot be measured due to infinite SWR being out of range of the meter.

==========
Just for info :
To watch TV and switch channels from a remote location in the house other then the location where the digital sat rx and another TV set are located , I have installed a piece of consumer electronics costing equiv US $ 150.-

It comprises a 2.4 GHz tx at the digital sat rx site and an identically looking 2.4 GHz rx at the remote location . This link takes cares of picture and sound to be carried to the remote location.

In addition ,the enclosure of the above 2.4 GHz rx accomodates a 433 MHz LPD (low power device) link tx receiving its input from an infrared handheld device at the remote location.
The enclosure of the 2.4GHz tx accommodates the 433 MHz LPD link rx ,its output being fed to a separate infra red output device which is fitted in such a way that it can be seen by the infrared receptor of the digital sat rx.
This facility makes it possible to select any digital sat rx channel from the remote location .
The infra red handheld device at the remote location can also control the audio volume of the TV set at the remote location through this TV set's own built-in infra red receptor.

Hence there are NO cables (coax or otherwise) required between the 2 sites
I imagine this type of kit is also available from outlets in the USA like Ratshack.

In Europe (CEPT countries) the 433 MHz LPD band is used for various unlicensed devices including car key fobs.

Note : If the above remote TV set is installed in a kitchen equipped with a microwave oven ,the oven when switched on would cause interference to the

2.4GHz picture/audio link (although only the picture will likely be affected).

To check resonant frequency of an antenna trap -

Put a 1-turn loop around centre of trap, closely coupled.

Extend the loop wires to the 259B or Autek via 6 or 8 or 10 inches of
loosely twisted pair of wires.

Switch meter to Z range.

Initially the meter will read a very low value of Z.

Slowly vary frequency until impedance increases very sharply to several
hundred ohms. Vary frequency for maximum impedance indication.

Resonance will be very sharp. If the meter should go past full scale
reading, slacken off the loop.

Hello,
I've made a VHF receiver and I want to add a PLL to control the VCO. In order to calculate the loop filter, I need to know the VCO gain, but I don't know how to calculate (or measure) it. For information the VCO is a colpitts oscillator.
Could someone help me ?

Thank you in advance ;-)

Sorry - my mistake. Resonance occurs at highest Z, so
it won't work the way I posted. How about this:

```
MFJ---Trap--A--50ohms-------+
S0- |
239---------B---------------+
```

At points A & B you connect an RF probe to measure
the RF voltage across the resistor. At lowest voltage
you are at resonance. I've never tried that, but it
might work.

> Could someone help me ?

VCO gain is basically the first derivative (slope) of the tuning voltage vs. frequency function. It's rare to find a VCO that tunes truly linearly, so it will differ over the tuning range.

There are two ways I've plotted the tuning voltage vs. frequency. One of them is the obvious way; connect a frequency counter to the output of the VCO (taking care not to load the VCO output inappropriately; you'll want to simulate the conditions under which the VCO will actually be used), and then vary the tuning voltage very carefully, plotting the voltage vs. frequency. From this you can calculate the tuning gain.

Another way, and it might be easier, is to include the VCO in a PLL. Guess at the parameters and you'll probably get a loop that locks up. As long as the loop is in lock, you can vary the frequency by programming the PLL and measure the tuning voltage. As long as your loop reference is reasonably accurate you'll get at least as good results as if you used a frequency counter and I believe this method is better since you're measuring the VCO gain in the system.

Enjoy!
Dana K6JQ

i just read this thread and had a few thoughts. i don't know what kind of interference you're dealing with, nor do i know what restrictions are placed on your competitions.

i was thinking about front end overload, also. the types of interference vary in different countries, but those paging towers and, taxis, etc. all play hell on a front end. you really need a spectrum analyser to figure out what you're deaaling with.

as for those ceramic resonators, they're ok, but in the better receivers, they're followed by if xfmrs to get rid of the spurious response of the ceramic filter.

since you are thinking of just starting from scratch, here's what i'd do if you're not bound by rules.

http://www.aerocomm.com
http://www.radiometrix.com

cost? i dunno. i figure if you can afford one, good. then you can spend more time on the robotics and weaponry.

if you can use these, the question becomes a matter of whether you can retrofit one of these in time. i'm not ready to look into using them yet and therefore haven't gotten into the details. so i don't know what

you'd have to do to get a PWM signal in and out, but since they handle a higher data rate (1 Mbps) than std R/C PWM, you could bust the PWM signal up into little "chips" and reconstruct it on the receiving end. maybe an integrator/LPF would be all you need. on the other hand, maybe you can just send" the PWM directly. I'm sure the applications engineers could help.

hope this helps.

mike

Have your circuit-building activities led you to a career? I know Roy does RF engineering consulting work and is most famous for NEC code for antenna simulation. Any others? Is anyone here working at Perkin-Elmer? OI Corporation? Or any of the numerous smaller instrumentation companies? I can see what types of engineering careers homebrewing can lead to: not only RF, but also instrumentation/controls. In fact, many of the projects in the ARRL books are electronic measuring devices.

I graduated with my BSEE from UIUC in 1996. If I had been a ham radio operator and a homebrewer as an undergraduate in electrical engineering, I would probably have invented a time machine by now. :)

In fact, if it were not for ham radio and the Northern Virginia QRP group, I would have no business in EE today. Although I had originally intended to study RF engineering when I applied for graduate schools last year, I changed my mind and switched to the control systems specialty when I enrolled. Working on simple electronics projects (like a car battery tester and electromagnetic field monitor) opened my mind to other parts of EE. I saw that instrumentation and control systems are used in a much wider variety of industries than RF systems. I saw instrumentation/controls as an area that would have value in many areas outside telecom and defense.

Last semester, I designed and built a better SWR/wattmeter, one that could handle 100W like the MFJ versions, provide good measurements at QRP power levels, AND provide good resolution at high SWR levels. (I owe a thank-you to those of you who helped answer my questions.)

I am scheduled to graduate with my MSEE next year, but I am willing to delay my graduation for an electronic instrumentation engineering position.

763. Re: Has homebrewing led you to a career?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-07-31 21:00:51 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vij0s4jklcm896@corp.supernews.com>
Source record: 33780

Much as I'd like to take credit for playing any part in the development of the NEC codes, I can't. NEC-2 and its successors were developed mainly at Lawrence Livermore National Laboratory, and I had no part in that work. What I did was to first take MININEC (developed independently by John Logan and Jay Rockway) and make a usable interface for it. This program was called ELNEC. Later, I adapted the interface to NEC-2, naming the result EZNEC. ELNEC and EZNEC are really interfaces to the underlying calculating engines, which I had no part in developing.

I'll second Jason's reminder that there's a lot more to EE than RF. In my career, I've designed video test equipment including a very fancy TV camera, slow scan video instruments, switching power supplies, micropower vehicular speed recording and data logging equipment, very high speed pulse generation and sampling gear, high precision samplers, delay line compensation networks, infrared imaging equipment, time bases and other oscilloscope circuitry, and many other types of equipment. Traditional RF circuitry is more a part of my hobby than my career, although as Jason said, I've done some consulting work in that field.

And those of us who are engineers weren't born that way. I began as a ham when I was a kid, studied for and got my FCC commercial license, worked as a broadcast engineer and then chief engineer, went through the Air Force radar school, worked as a radar technician, and fixed radios, TVs, and telephone answering machines before working my way through school (with a bit of help from Uncle S.) first as a technician then as a design engineer. People following a path like that can "get off" at any point where the work is satisfying and interesting.

Right now and for the foreseeable future, it looks like there are opportunities in EMC (electromagnetic compatibility -- EMI reduction). With the proliferation of wireless devices, the EMC environment is getting tougher and tougher. Antenna design seems to be in steady demand. And there's plenty of work for a good analog or analog/digital engineer, and technicians, in a wide variety of small, mostly startup companies. I haven't seen age as an issue -- in fact, it seems that there aren't many young folks learning some of these skills. If you can do the job, you should be able to get a job.

Thanks again for your input, John.
I only have these two r/c model transmitters to test against
themselves. It would be a remarkable coincidence if *both* were
defective to the same degree. I can, however, confirm that they both
put out almost exactly the same power as each other. I infer from that
that there is no problem with either.

>At your place, are range checks of both the Sanwa
>and Futaba R/C sets, on there own, not installed
>in anything, over 100 yards . Yes or No?

Yes.

> Yes or No?

Yes.

>At your place, are range checks of both Sanwa and
>Futaba with drive motors being controlled and
>running nicely, still over 100 yards. Yes or No?

Ah, well I haven't tried that one. Good suggestion. I'll do so as soon
as I have a colleague handy to assist!

>At the noisy Venue, while doing a range check of less than
>30 yards with all other competitors absent or their
>transmitters switched off in the Tx compound, do both
>your Sanwa and Futaba R/C sets play up?
>Yes or no?

No one's permitted to carry out such tests at the venue. As soon as each competitor arrives, all transmitters are immediately impounded and only released on a book-out/book-in basis under supervision of one of the organisers' technical bods and only then if no one else is using that frequency elsewhere in the building at the time.

>At The Venue, do other competitor's radio control
>sets play up like yours Yes or No?

It's a very common problem indeed, yes.

>At the Venue have you scanned the band with a
>simple crystal set type radio or fancy scanner for some
>bastard with a transmitter who is determined to give
>you, personally, a hard time?

It's a pity I sold my last spectrum analyser about the same time as I started this lark! Big mistake, that. :-(However, I'm given to understand the studio people have one and keep an eye open for any such 'irregularities'.

[other valid points noted and snipped]

Things are looking very much better this time than last. I've discovered a good many possible causes of the problems we had last time out and have remedied all those I've found. I've also carried out improvements suggested here by your good self and others. I'm leaving nothing to chance this time!

>If you are still having problems after all that,
>sorry Paul, I give up.

So will I.

Thanks for your input, Mike. Yes, the microwave band you mention is
forbidden. We can use either 40Mhz or some other band up in the
400-500Mhz region somewhere.
I'll check out the links you provided.

Rush Limbaugh is always talking about this kind of bitter advice. Young people who are interested in getting into the radio business often ask their more senior counterparts, only to be told, "you better not get into this business -- you'll get eaten alive". Sure, it's hard, but if you ask someone who hasn't been successful himself, that's the kind of answer you'll get. Rush encourages would-be radio personalities to follow their dreams.

My philosophy on this type of thing is simple, and mirrors Rush's. If you do what you love, you'll be great at it. If you do what you don't love, you'll be mediocre. I had a girlfriend who was fascinated with psychology but took computer programming because she thought that was where the money would be. When she graduated she got a job she didn't like, and she didn't do very well, even as others did great in the same field.

To his credit, Mr. Squire did mention that someone who is passionate can do fine in his chosen field, even in hard times. I suppose if you've made up your mind in advance that you will be mediocre no matter what you do, then you might as well choose a field where mediocrity is punished the least, but I can't imagine living my life like that.

TES> 1. There are now very heavy market forces toward
TES> globalization. This means most technology jobs at the low
TES> and medium ends of the scale are being outsourced to
TES> third-world countries such as India, Mexico, and China.

Not to slam those countries or the accomplished professionals in them, but some types of work are more easily outsourced than others. Some of the most exciting work in technology fields is not exported.

TES> 2. There is rampant age discrimination in the field, and
TES> companies make it extremely expensive to prove such. Your
TES> chances of getting and keeping an engineering, software, or
TES> electronics job diminish greatly upon reaching the age of
TES> about 35. Your chances of such upon the age of 40 are such
TES> that a great amount of luck is called for.

This type of bitter (though generally true) remark reminds me of the lament of many single people. Sure, the vast majority of people you could possibly date won't work out, but you only need to find a few good fits in your entire life. Why be content to have an ordinary job, or an ordinary mate? The median age where I work is around 40, and our most cutting edge research is being done by people in their 50s and 60s. I'm 37 and I think I'm currently the youngest in our department.

TES> 3. Engineers and other "techies" have now become such a
TES> commodity that at many large companies treat them with a fair
TES> degree of contempt. Basically, Dilbert is more true to life
TES> than you might think.

True enough. Drunk, drooling men in bars are a commodity, too, receiving a good deal of contempt. When I set out to meet a woman, I make sure I'm not drunk and drooling (or even in a bar!). Likewise, when I apply for a job, I emphasize my unique abilities.

TES> 4. Craftsmanship is no longer a guarantee of immortality.
TES> Whatever dedication you place into your work will largely
TES> wind up in a landfill eventually.

Our landfills are full of successful products which have made fortunes for their creators, but I assume you're talking about projects being scrapped instead of completed. Again, my outlook is far more positive. If you can make machines bend to your will, your skills will always be in demand.

TES> Yes, this all sounds bleak. But this is life.

TES> In your point in life, I would recommend working your way
TES> through an accelerated liberal arts degree at a community
TES> college where you could possibly obtain some credits for life
TES> experience. Take practical courses: accounting, computer
TES> programming, 4 units of a foreign language, and how to teach
TES> English as a second language. Take some arts: pottery is
TES> generaly easy. Take math up to integral calculus. Then fill
TES> your mind with civics, western history, and culture.

TES> At that point you should be prepared to teach English in the
TES> Peoples' Republic of China.

Wow, this sounds bitter. The original poster expressed enthusiasm and an interest in a specific field, and now you'd have him put his time and energy into just about everything else! Every one of the jobs you mentioned has a dreary place for its mediocre practitioners: accounting sweatshops, computer code grinders, etc. And for goodness sake why take up an art just because it's "generally easy"? I'm starting to wonder if Mr. Squire has ever felt like doing something and then done it and enjoyed it and felt good about it.

To the original poster of this thread, I'd say, examine your reasons for pursuing electronics. If it's because you think you'll enjoy it

and really dig in, then do that. If it's just because you heard that's where the money is these days, take a lesson from my old girlfriend (and me, and Rush Limbaugh) and do something you're passionate about.

David

Homebrewing led me directly to my present job and has gotten me many others as well. In fact, I'm not sure I could cite a job where homebrewing wasn't a factor in getting the job.

A great thing about the job I have now is that the bosses recognize the link between homebrewing and learning, so I get to take parts from our stockroom for my projects.

In article <bgbgekgbp1@reader10.wxs.nl>, damien.teney@sobelairva.net
says...
> Okay, but as it isn't constant over the tuning range, do I have to use the
> average value of it in the formulas of the filter ?
>

Usual practice is to design the loop for the geometric mean of the VCO's
frequency range.

Say you have a VCO covering 1000 to 2000 MHz. The geometric mean is
sqrt(1000*2000), or 1414 MHz. Either check the manufacturer's data
sheets for Kvco at that frequency, or, if that's not practical, apply
enough voltage to the tuning line to reach, say, 1409 MHz. Then bump
the voltage up to reach 1419 MHz, and note the difference. Kvco is then
determined by dividing the voltage difference by 10 MHz. It'll be an
approximation to the true derivative, of course, but that's fine because
the VCO's nonlinearity will normally represent a far-greater source of
error.

The most common 'gotcha' here is confusing radians/volt and Hz/volt.
Some PLL data sheets and textbooks use radians, while others use hertz.
Since the difference is more than 6:1, you want to make sure you get
this part right, or you'll end up with a broadband jammer.

Jason,

Congratulations on your choice of career direction. I wish you well. I'm not sure whether or not homebrewing makes you a good engineer, or if being a good engineer triggers something that makes you homebrew. Bob Pease (I think) once said something to the effect that the really good engineers he'd hired were the ones who continued to do engineering things even when they weren't at work. (My apologies to Bob if I've misstated his intent.) The idea is that doing technical things is a passion for some of us. We'd do these things even if we don't get paid. Homebrewing is a passion.

A general observation - many young engineers (and far too many older engineers) have little or no hands-on experience. They can model something and run great simulations, but are stopped cold when it comes to actually troubleshooting hardware. Knowing how real hardware works will give you an edge. Homebrewing is a great education.

I think that homebrewing gives very good experience.....this is what got me in the door at both Rockwell-Collins, and Motorola. Now, I am working at an engineering firm. One thing that I've observed over the years.....when you are debugging a new design in the engineering lab, it is almost the same as working on a project at home. It wasn't until I worked for a crystal filter company, that I realized that "gimmick" capacitors are used for fine tuning the filter's characteristics before filling the filter with potting compound. Homebrewing is great!

DBT> same field.

While I do not consider Rush to be a proper role model for children and
polite company, what you are saying is true to a point.

But consider this: the 5 percent who enter the field for love wind up to be
the
people who clean up after the 95 percent who enter the field for money, and
those 5 percent would prefer to do something creative rather than clean up
the
team's garbage so the project actually functions. To make things worse,
the
lead is generally a professional manager with nearly non-existent skills in
the

people being supervised, which makes it extremely hard for the manager to tell who is actually doing the work in a team and who isn't.

This type of nonsense is truer for engineering than for other fields, so these
are the dues which a person contemplating entering this field should be prepared to pay.

DBT> To his credit, Mr. Squire did mention that someone who is passionate
DBT> can do fine in his chosen field, even in hard times. I suppose if
DBT> you've made up your mind in advance that you will be mediocre no
DBT> matter what you do, then you might as well choose a field where
DBT> mediocrity is punished the least, but I can't imagine living my life
DBT> like that.

Wake up and smell the coffee! In the real business world, mediocrity is indeed
punished the least, at least most places. After 15 years of working in tiny startups
run by corrupt managers, dysfunctional corporate cultures, and co-workers who
took pleasure in sandbagging the true believers, I snapped. I resigned without
notice, filed bankruptcy, and in general stayed away from engineering for about
18 months. I bounced around some shelters across the country, found work making
sandwhiches and cappucinos, washed dishes, cashiered at Toys R US; and I
also took antidepressants and psychotherapy.

I was prepared to stay like that forever, because I had completely lost my trust
in the engineering workplace. No matter how talented or passionate I was, at
the start of that time away my hands started shaking at the mere thought of writing or debugging another line of code. And people actually gave me far more common courtesy as a barista and cashier, than I ever obtained as a software designer up until that point in time.

After 16 months, life was starting to become comfortably routine, my therapist
noticed this and advised that I take a gamble and shop my resume, just once,
to a headhunter. I did so, and I thought nothing of it for the next 2 weeks.
Imagine my astonishment when a Fortune 500 wanted to fly me down for an interview,
complete with rent-a-car, an overnight stay at a Sheraton, and 5-star dining! Their
mission statement placed integrity first above all other things (with, of course,
a honest days work being consider part of integrity).

During my interview, I was very candid about my experiences without being overly
negative about them. I basically told them that they got my attention, that there was
quite I lot I could do for them, and I was ready to take a chance on them if they were
ready to take a chance on me. Not only did I get the job, but I wound up being paid
more than I ever did in my life for doing less than I ever did in my life. I was actually
starting to get bored, so I wound up volunteering to write tools for people, and I brought
to bear all my small-company experience to bear on this. I've been there for a few years
now, being allowed to work with very loose supervision, in the process generating results
equivalent to a small team and gaining a lot of respect in the process. This has helped
all the other areas of my life: I've actually developed enough confidence in my career
and in myself to date, marry and start a family.

Moral of the story: Passion for your work is only effective when reciprocated with
respect and empathy from your work. Following your dream can otherwise wind up
becoming following through a nightmare.

DBT> Not to slam those countries or the accomplished professionals in them,
DBT> but some types of work are more easily outsourced than others. Some
DBT> of the most exciting work in technology fields is not exported.

Untrue. Untrue. Untrue. These countries have us beat regarding education of thier
elites, who with world-class MS and Ph.D. degrees based on European standards
are more than capable of performing technically challenging and original work.
These people don't need passion, they're satisfied to do as much as the most
passionate person in our country, for a living wage in thier country. And they're
willing to take the abuse of the workplace because compared to their cultures,
our expectations of personal fulfillment through work are, quite frankly, infantile.

Sorry, the comparison doesn't wash. You can be a great, dapper, neat,
sociable, and well dressed engineer, and still be treated with a great
deal of contempt for not having the cojones to go into management, sales,
marketing, or legal. Engineering has actually become an entry level job
in the average organization regardless of size. Anyone who stays in
engineering after a few years is considered to lack ambition and therefore,
after that time, becomes layoff bait.

Again, I ask, where's the immortality? Lawyers make laws. Doctors
prolong life. Soldiers get monuments. Owners make endowments and
fund chairs.

I have decided that I would rather seek immortality through my children
than attempt further to seek immortality in my chosen field. While the
work is great right now, and my passion for my work is back at the

level it used to be, I have learned my lesson: passion has to be tempered with an awareness of the real world.

DBT>
DBT> TES> Yes, this all sounds bleak. But this is life.
DBT>
DBT> TES> In your point in life, I would recommend working your way

DBT>
DBT> TES> At that point you should be prepared to teach English in the
DBT> TES> Peoples' Republic of China.
DBT>
DBT> Wow, this sounds bitter. The original poster expressed enthusiasm and
DBT> an interest in a specific field, and now you'd have him put his time
DBT> and energy into just about everything else! Every one of the jobs you
DBT> mentioned has a dreary place for its mediocre practitioners:
DBT> accounting sweatshops, computer code grinders, etc. And for goodness
DBT> sake why take up an art just because it's "generally easy"? I'm
DBT> starting to wonder if Mr. Squire has ever felt like doing something
DBT> and then done it and enjoyed it and felt good about it.

Read again what the poster is saying: he's tired of dead end jobs, and he wants
to do something, anything, that is different, but doesn't exactly know what that
is. My advice is designed to shake up his life in ways no one, not even
he, can predict... that's what's part of the fun. Consider:

1) A liberal arts college program is the very best way to begin gaining the perspective needed to decide one's life's ambition. I emphasize some courses
for the sake of later survival, but these should not dominate the real work of the
curriculum, which is to develop an understanding of the greater reality of the
world beyond work.

2) Even dead end jobs can be compensated for through the development of the pleasures involved in living the life of the mind. These jobs can even be a good
break from studying and pondering and questioning.

The orignal poster may or may not be able to find a better job after finishing
a completely technical program of study, but if the technical market is dry or

his chances of psychological survival are not significantly increased. However,
a liberal education mixed with a sprinkling of additional survival skills will make
him far more adaptable to stagnation or even outright adversity.

3) I forgot to mention the other side of finding one or more arts or activities
which are generally easy to learn... these things are also generally easy to teach!

Being able to teach a few skills which are easy to master tends to open more doors
than you might think: it endears one to the vulnerable and gains respect from
those who care for them.

4) I'm not being cynical regarding teaching English in the Peoples' Republic. I have
been given the same advice from a dear friend of mine, long since passed away, who
did this and wound up teaching far more than just English in a classroom.

You're teaching not just about what you speak, but also about your entire life.
This is an experience which forces one to re-examine one's entire life from every
angle, while at the same time developing confidence in all the smaller things about
life by sharing them with other people who consider them exotic and entertaining.

>

Our friend, however, has nothing to lose by doing the completely unexpected.
My presciption for him is that he undertake a genuine adventure, with adequate
preparation up front for all the surprises he will certainly encounter along the way.

I was on the verge of doing this myself until I took the coward's way out and gave
engineering one last chance. But I'm happy and reconciled with who I am, I have

love and family, and in general I am more content even thought I did not dare take
the road less traveled.

The Eternal Squire

Jason,

Take my advise, graduate first then look for a job! You could finish up with
a job going belly up and have no MSEE.

Play it safe, get the ticket first. I see this happen all the time.

Good luck & 72/73

Jack

Very true - though only if you can join those two different kinds of experience together.

Modern electronic designs spend most of their time in the computer, being laid out, modeled and optimized, before the soldering iron is ever switched on. Then you build it, and it works first time. It has no other choice.

Lots of old-timers will say "Oh yeah?"... but it's becoming increasingly true. The aim in modern electronic design is to give the finished products absolutely no other choice but to work.

If you've never had any contact with this modern approach, you may be surprised by how close it's possible to come to that ideal. Things that used to be exclusively practical, like the effects of component value spreads and temperature, can now all be done in the computer. It's not perfect, but it can usually show you the weak points in your original design, so then you can re-work the design to make it more tolerant.

Thinking about it some more, that's actually *three* different kinds of experience that need to be joined up. The first is design, which is essentially a creative process. Circuits don't design themselves - someone has to have the basic ideas first, and both experience and creativity are needed there. Then a computer can help refine the design (for example filter synthesis).

So we're actually looking at a three-step process:
DO
1. Design
2. Model
3. Build
LOOP UNTIL (ItWorks)

The DO...LOOP thing is a way of saying that it's a learning process. The key is to know how to feed *all* your real-world experience back into that process, so your next design will be a better one, and your next model comes that much closer to real life. RF and fast digital circuits can be tricky... but once you've mastered those tricks, you'll never lack for employment.

> Homebrewing is a great education.
>
If you decide to *let* it educate you! Hams have a choice about that -
but tomorrow's professional RF engineers don't... not if they want some
control over their lives.

Yep right, my formulas use radians/volt, so, how can I transform the hz/v
value that I got with your trick, to rad/v ?

omega = 2*PI*f

that's where the >6:1 came from. 8-)

Thank you for your reply but that is what I did except
I had a 2-turn loop and 50 ohms in series.
My common sense told me that if I again read that 50 ohms
approximately, then the open-ended trap is not loading the
loop ie it is high Z. Thus the MFJ reads SWR=1 due to the
50 ohms. This resulted in >7.15MHz.
You suggest no series resistance ie the MFJ sees more or
less a short with virtually no inductance at LF and when
increasing freq to reach there is a minimum of absorbtion
from the loop or alternatively speaking, a high reflected
impedance.
I tried that and yes, I get a sharp Zmax at 7.00MHz and no
other peaks or dips.
However, coming back to a swept test with an IFR 1200S
the frequency is 7.15MHz ; the same as my assumed point (b)
with the MFJ in my original correspondence.
I presume I canot attach a jpg in a newsgroup so I will
email the jpg to you.
Maybe all this is academic as adjustment of antenna legs
can easily compensate. Nevertheless, precision is my game.
Regards.

Subject: Re: Trap test trauma

| To check resonant frequency of an antenna trap -
|
| Put a 1-turn loop around centre of trap, closely coupled.
|
| Extend the loop wires to the 259B or Autek via 6 or 8 or 10 inches of
| loosely twisted pair of wires.
|
| Switch meter to Z range.
|
| Initially the meter will read a very low value of Z.
|
| Slowly vary frequency until impedance increases very sharply to
several
| hundred ohms. Vary frequency for maximum impedance indication.
|
| Resonance will be very sharp. If the meter should go past full scale
| reading, slacken off the loop.

I agree, homebrewing is great. It actually got me interested in taking engineering in College. I started homebrewing partially out of interest, and mostly because I couldn't afford real gear! After a few simple transmitters, receivers and stuff, I realized that I REALLY enjoy this stuff, so I decided to go with it.

One cycle = 360 degrees = 2*pi radians, which makes
radians/volt = 2*pi*hz/volt.

My father, one of the great mechanical design engineers, used to
tell the know-it-all recent graduates that an engineer was just
a technician with no practical experience. It holds true in most
fields. He was very strong on getting his EITs and co-op students
into the machine shop to make things and to work with the people
who had to use them.

He turned out some awfully good engineers by using those methods.

A good *design* engineer has a deep understanding of fundamental principles based on, but not confined to, mathematics (a good math program like Mathcad is a very powerful tool). This is a lifelong process, and not just part of a classroom curriculum. He has skills (but perhaps not great expertise) in the difficult process of computer modeling and analysis.

He has good intuitions about how things work. Intuition is always very important, but should not be overemphasized. Too often intuition, by itself, can be a mental "trap" that we fall into.

Design engineering work is not the predictable straight-line process that some think is so desirable. A good engineer knows the benefits of being wrong from time to time.

He is also a "practical" person who is competent at a work bench. He is *highly* skilled in the usage of measurement equipment to evaluate, troubleshoot and modify what he has designed (and modified).

He is also comfortable within a design *group* environment. The concept of the "lone wolf" engineer died a century ago. However, original ideas very often come from one individual. On the other hand, orthodoxy (the group mentality) can be an engineer's worst enemy (ask NASA about this).

Homebrewing is a very valuable experience, unless it involves only "copycat" engineering. "Learning" from what others have done is not the same thing and is of a higher order than "imitating" what

others have done.

Hello, Jason!

Having had electronics as a hobby / passion since I was given a Knight Kit 21-in-1 electronics 'lab' while 10 years old, I ended up choosing a college (IIT), major (EE), and career accordingly. While some career fields can lead to burnout, the terrific diversity of electrical engineering has always left me learning and enjoying more. Modern field programmable logic, high performance CPUs, signal conversion, and more open avenues that were undreamed of just recently. And homebrewing lets you get your learning and experience with portions of the field that you may not be using at work but can pay great dividends in future projects.

Most jobs that have hired me - and the resulting seniority there - have been due to my range of proven capabilities (analog, RF, digital, FPGAs, embedded processors; software and hardware; telecom, test and measurement systems, semiconductor production, motion control; etc.). Amateur radio has helped a lot (since building my own transmitter when 16) as has involvement with the Experimental Aircraft Association and other active groups which give you a chance to jump into projects and learn.

Back in school I was amazed at some engineering students who wouldn't know which end of a soldering iron to grab. Homebrew projects can make a world of difference in practical knowledge.

Best to you and your career - the world always needs more engineers with passion, skill, and knowledge!

Jim Horn, WB9SYN/6 (Love what I do - and get paid, too!)

With the piece of fiberglass IN the cup of water in your first test,
you have no idea which got hot. They will always end up the same
temperature because they are touching.

A far better test would be to put a cup of water in the microwave, and
the fiberglass NEXT to it. If the water gets hot and the part doesn't,
it is potentially OK.

Your second test should never be done, because (if you were right
about the material) there was nothing in the microwave to absorb the
energy, and if it did absorb the energy, you would have unexpected
results.

Note that the microwave test may not be valid for all RF frequencies.

Carbon fiber is much more expensive, and if the part you bought had
any, they would have made a fuss over it.

Happy trails,

I'm looking at my worn copy of the 1966 ARRL handbook. On page 124 is the Junior Miser's Dream receiver. The 1966 version used two International crystals for the IF filter: one at 3300 kc's(I know it's kHz now) and the other at 3301 kcs. On page 139 is the HB-65 five band receiver which didn't have a crystal filter in the IF section but did have a double tuned front end. There's also a four transistor regenerative receiver on page 120 which used SK3004 and SK3006 transistors. The two SK3006's are in a two transistor detector-oscillator configuration. Hi chaps,

Can anyone suggest a suitable material from which to make an
ultra-flexible mobile whip antenna say about 3 to 4 feet long. I need
something that can be bent to 90 degrees at a very small radius and
still return to reasonable straightness.

Thanks,

p.

It is probaly the color, a lot of color used to color fiberglas and other plastic materials are based on graphite.

I think thin piano wire will give the best results. Place a lot of them in a flexible tube to gain some thickness and have them silvered for conductivity - or add a stranded copper wire.

Spring metal strip may also work, especially if you can manage some type of hinge at the base that allows it to turn when sideways force is exerted, or if the force is in one plane.

Thomas

Sure, get some 1/4 inch fiberglass rod, loosely helix some #22 wire up the length, and secure with some heat-shrink tubing. You can bend this into a near circle.

Try telling that to the people who graduate with 5 or more job offers.
Do you really think these individuals waited until graduation day
before seriously conducting their job search? Of course, if you know
of a silver bullet for figuring out which specific companies are
actually hiring at any given moment, let me know. (Such silver
bullets from everyone else on this newsgroup are welcome.)

> You could finish up with a job going belly up and have no MSEE.
> Play it safe, get the ticket first. I see this happen all the time.
>
It sounds like you think the credentials are the most important thing.
The problem with this thinking is that many with this attitude end up
becoming the engineer who looks good on paper but can't engineer
his/her way out of a paper bag. What I learn and accomplish are the
most important things. You could argue that the BSEE is essential,
but I already have that.

The irony of my graduate school experience is that I feel like I have
accomplished more in one year than I did in 4 years as an
undergraduate despite the fact that UIUC (my undergraduate school) is
vastly superior to GMU (my graduate school) at hardware and controls.

If I felt that my MSEE and GPA were the #1 thing, I would not have
been able to take control systems or signal processing classes. I had
NO control systems background as an undergrad, and my signal
processing background was nothing more than earning a C in the
3-credit-hour introductory signal processing class. GMU, like all but
a handful of schools, is weak in control systems, and my graduation
date may be delayed by insufficient control systems course offerings.
Then there's the most important thing: If I defined myself by
credentials, then I would NOT have been able to do last semester's
independent study project, as it was very time-consuming and
difficult. If you think that one can become competent in an
engineering topic simply by plowing through the class, then I have
some Enron stock to sell you.

Bottom line: Because my MSEE is not that critical, I can afford to
take some calculated risks. Isn't that something every engineer needs
to be able to do?

Hi, I am looking for advice on how to integrate a PIC microchip with a ham radio transciever. I will use this in a robot. I am looking for 100 - 300 mile range. I have a ham radio license.

Thanks for the help

what is a tight bend? music wire comes in diff sizes and the number in
the tube and how tightly the tube conforms to it will have an effect on
the flexibility.

a shorty could be made from those old storm door return springs inside
shink tube which is what i'd suggest putting the music wire in. use the
copper wire, i'd think. seal the ends from the elements, except for fire
:-0

short segments of wire(s) with return spring segments as connectors?

OTOH, mobile whips with base springs are common enough if all you're
worried about is those friggin' trees hanging over the road that no one
cuts, or the drive through windows. why such a tight bend spec?

regards,
mike

aw hell.

i hope you're the AH i figure you for. if not, and this is just innocent
ignorance (is that possible?) don't take this too hard. just listen.

<!-- if you are an AH... -->
<script language="AH_Blaster">
<flame level=150%">

stop bs'ing.

1. if you have a license, you should know that you can only control
cars, boats, and aircraft at 1 watt which hopefully keeps the model
within eyesight.

i don't know what's legal for bot's, but AFAIK the max power will be .75
- 1 watt.

2. are you stupid? if you transmit that far or even just out of
eyesight, you'll

a) mung any legit R/C craft affected by your signal.
b) probably hurt someone with your POS robot.
c) cause a legit craft to hurt someone.
d) interfere with anyone communicating.

>
> Thanks for the help
>
here's your help:

buy the most expensive books you can get until you're broke and can't
afford dangerous toys. go into debt to keep you out of trouble in the
future.

buy a cheap pic and glue it to a radio with no power cord or battery.
now it's "integrated."

</flame>
</script>

<noscript>
read a pic data sheet. PIC12F84A is pretty basic. get the software to go
with 'em.

figure out what you mean, next.

then ask more specific questions.
</noscript>

Must have been a real stinker ;@}.

Obviously only conventional R/C stuff is power limited in the way you describe.

The op stated Ham radio gear,from which I assume SW, and not subject to the same limitations power wise. However first problems he needs to solve are probably getting a high enough data rate to know what the robot is doing. Video is doable, but pretty hard over SW, I don't know what bandwidths Hams are allowed. Integrating to any micro is simply a case of converting data into a format that the micro can understand, ie NRZ serial, or pulse length coded. I would start by looking at something like the FX929 from CML. it handles the micro to radio interface, and includes FEC etc, it is designed for short packets. failing that packet radio, which, as a Ham you should probably knwo more about than I do, is designed explicitly for data comms like this. You can then choose to implement your own direct control scheme of the robot, ie PWM motor controol or what have you, or read up on R/C servos. these are pretty simple, IIRC 20ms between pulse, and pulse of from 1-2ms to set the 'position' of the servo. Use the micro to convert complex instructions into servo control signals.

Yeah, sorry chaps, I should have better defined what I meant by 'very
small radius'. I compete in radio-controlled model battles, so the
model stands to get fipped upside down from time to time in a very
bruising environment and it already has a very low ground-clearance,
so using a spring as a base mounting won't help much, I'm afraid.
We're talking about radiuses of as little as 5mm! How about the
specific grade of stainless steel in wire form that springs are made
from? I know where I can get hold of some of that....

Better pick up a copy of the FCC rule book and read it thoroughly before
embarking on this project to insure that it is legal.

The alloy is Type 301 (17% chromium, 7% nickel stainless steel) hard drawn wire, or even better is a 17/7PH (precipitation hardening) grade that our firm once produced for tank aerials, that also may take a few knocks. ;)

Both (especially the PH grade) need a final heat-treatment (420C for a few minutes IIRC) for ultimate spring properties, but to get such a tight bend you'd need quite a thin wire. It's a matter of the proof strain or limit of proportionality, how much the outer skin can stretch without taking a permanent set, compared to the neutral central axis, on the bend.

You might try a section from a steel tape measure.
(Just don't select one of the cheap, Made-In-China plastic/mylar
ones. HI!HI!)
Additionally, try to mount the antenna in a "well" on the robot.
Even a well of 5-10 mm will help out.

806. am transmitter help!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-08-02 17:43:43 UTC
From: bobinphx <rbelisle1@cox.net>
Message-ID: <t_SWa.34180$Ne.22532@fed1read03>
Source record: 33723

Hi folks,
I've been lurking here for awhile and this is my first post.

I own a whole bunch of older tube radios. The majority of them are AM BC/SW. I found a great site on the internet that broadcasts old radio programs (http://www.yesterdayusa.com/) via the internet. Its great to listen to while I answer emails etc, but when I am away from the PC, I cant listen to it......So,,, I hooked up an older tube Eico 324 am signal generator to the headphone jack of the PC and attached my SWL indoor random wire antenna (it runs around the ceiling of the home office I have (about 12 feet on each of the 4 sides, plus 6 feet of lead in)... Well,,, low and behold, I now have a great little transmitter that transmits on BC and SW. It works great in all rooms (the old radios are spread around the house).

Now to the question. What or how can I match the audio input to the input of the signal generator?
The manual for the signal generator suggests a 70k ohm AF (audio freq) input.
I am guessing that the PC headphone jack is 8 ohms, big mismatch.
What issues will this cause??????
The manual also has modulation notes that state "External AF voltage required for 30% modulation at 1mc rf setting (1000 cps signal) aprox 3.0 volts" What the heck does that mean????

I am also unsure of how to match the antenna to the signal generator. The manual does not state what the output could or should be.

Note that the generator does not run hot and has been recapped and calibrated, to the best of my abilities!!!

I am a novice in terms of RF, but have been around TTL logic and have a good general (read self taught) understanding of electronics. I am concerned that long term mismatches may cause problems with the signal generator (I know enough to be concerned, but not how to insure my fears are groundless, for the issue is fixed.)

If anyone has any ideas they would be appreciated.

Thanks in advance
Bob in phx

he'd have to know what i said about type of craft and power limits to
pass the technician class test. there's a few high data rate tranceivers
ready to go and certified that will do this. the vagueness of the
question, range, and just the mention of the license (who asked for a
qualifier) scares me.

That's a pretty tall order for a reliable 24/7 communications link to a robot on the ground with a short whip antenna unless you use a satellite link of some sort.

The signal generator will run into any type of load without harm. Don't worry about matching it to an antenna. Just don't go too long with the antenna and while you probably will not get into any trouble , you are suspose to stay within certain frequencies. I think anywhere in the standard broadcast band will be ok if you keep the power to under 100 miliwatts. Probably more than the generator can put out anyway. As long as you are not causing any problems in the local area and staying below 2 MC or so the FCC has too much other stuff to worry about .

If you are plugging the audio from the sound card to the generator and it sounds ok, don't worry about matching the 8 ohms to the generator. Usually going from a low (8 ohm) impedance into a high impedance is not problem except maybe getting enough voltage to put into the generator. The "External AF voltage
required for 30% modulation at 1mc rf setting (1000 cps signal) aprox 3.0 volts" means that to get a certain ammount of audio on the output signal you need 3 volts out of the sound card. Those numbers are a standard for testing a receiver. Again if it sounds good don't worry about it. If the audio is too low on a receiver then put more audio into the generator, if it is distorted then cut the level of the audio down some.

Y'know, this is the first ham radio operator I've ever encountered who
DIDN'T sign a radio-related post with his callsign.

Makes ya wonder, doesn't it???

There speaks a man who obviously knows what he's talking about. Yes, I
believe we can order 301 from our guy in N. London who's very
accommodating on such matters. Thanks for a valuable steer!
Just one point, though: is stainless steel a reasonable radiator of RF
energy?

>
hi bob:

exactly. not to mention, you have data bandwidth limitations. you can't do much legally with OP's 50MHz. if you have a commercial link it's easy. for a commercial app we're looking at something along the lines of plant control. I'd opt for a setup where i could check the status of the bot via inet, cellphone, or satcom through a server at the plant interfaced with those precertified 2.4Ghz links. 1Mbps! tell your bots to do something. "hey, bot! pack a dozen cases of Bacardi." the bot should have enough brains to do that, right? "make 500 line number blah blah boards. oh yeah, and by the way, bot, here's the files. Have a nice day! :-)"

hopefully, there's someone around if the bots go nuts. at least someone who can shut 'em down before they drink all the Bacardi. assuming he/she hasn't drunk it all him/herself. :-0

so if anyone's alive when things settle down, perhaps they could page someone to pulease come in and fix things. if the plant computer detects no life readings it would have to page someone itself :-(

a POTs setup would be good in tandem with this setup. call your plant computer and use DTMF commands.

heh, heh... hope this works, right? better tell the security bot to be extra alert.

BRs,
mike

Back years ago (30 or so) there was an ad in a magazine about either a
loaded CB or 5/8 two meter whip about 36 inches long bent in a circle made
of the 17/7 material. Not sure what the whips are actually made of but
most are some kind of steel .

Does it have to be a whip antenna? Why not try a horizontal circular loop? Since you are working line of sight to the robot, the signal loss from going from vertical to horizontal shouldn't matter much unless your transmitter is extremely low power. A loop could be mounted inside a wooden or fiberglas body and be pretty safe from attack.

Is there anything in the rules forbidding your installing a jammer transmitter to cause the other bot to lose its command channel? Probobly a poor use of what little electrical capacity the onboard battery holds, but it would be one way of causing the other bot to freeze in place and become like a deer in the headlights.
thanks, John.

From: eternalsquire@comcast.net
Message-ID: <904dab11.0308022046.78061e06@posting.google.com>
Source record: 33739

Max,

I've been looking for a regenerative preselector on the net but can't find any. The few links I did find are broken.

I also looked at Q-multipliers, but there was no theory available for me to understand how I could construct one to work at RF, let alone couple it into the RF signal path.

Hints, please?

> 1967 ARRL HB had a receiver with an RF Q multipler.

I don't have access to this. Can you email me the schematic? Doing this is fair use, not a copyright violation.

Thanks,

The Eternal Squire

Amin,

I have some good news. I, too, had felt the need for a 3 khz bandwidth
tunable preselector, so I had been exploring gyrator-based filter circuits
where I substitute FETS for the resistors in the gyrators and then apply
voltage to the grids of the FETS for voltage tuning.

In a 3rd-order pi bandpass circuit in LTSpice using gyrators made from Maxim
1Ghz bandwidth op-amps, the voltage tuning part works nicely from up
to 30 Mhz, but the selectivity is about 150khz to 250khz. I do no better with higher
order filters, which I suppose is par since all I am using is an LC design
even though the L's are now all gyrators.

Looking for better selectivity, I happened about the Q-multiplier discussions,
only to find few circuits and no explanations. The few I saw indicate a fixed
tank circuit as the basis of the regenerative oscillator.

I think if we take a working example of an regenerative preselector and
subsitute a gyrator-based tank circuit, we can get a voltage tunable

rf regenerative preselector, which is what we both want!

So, if you can find the preselector, I can try to simulate it in
LTSpice
with the gyrator-based tank I've designed.

What do you think?

The Eternal Squire

Stainless steel is awful at conducting electricity - so it won't make a very efficient antenna. But how much it really matters, I don't know.

i always thought jamming would be a great weapon, but i bet it's
illegal. i'd like to see the rules for some of those competitions. i'd
think it would be fun to try sometime. i wan't to smash jay leno's bot.
come on. "chinkilla"? who writes his lines?

Paul's restricted to two bands, which i think stinks. he's probably not
allowed to jam. The band restriction i really don't like since it's a
bot competition not a DX contest.

BR,

If I believed this idea was workable I'd have implemented it by now.
You need to bear in mind that immediately beneath the polycarbonate
surface armor, there's a hulking great metal framework. Consequently,
sandwiching the antenna between the armour and the frame is going to
lead to unacceptable loss of radiated energy, I'd have thought. Unless
anyone knows differently..

>Is there anything in the rules forbidding your installing a jammer
>transmitter to cause the other bot to lose its command channel? Probobly a
>poor use of what little electrical capacity the onboard battery holds,

There's a considerable amount of battery power on board, actually,
since the peak current draw is well over 100 Amps at times. A few
milliwatts for a local jammer would therefore be a negligable drain on
resources. *However* as you've already guessed, jammers are banned, as
are EMP pulse type weapons and such like. The reason for this is very
sound, when you think about it: it makes for really bad TV. The
producers want to see as much *action* as possible. You ain't gonna
get that if everybody's disabled everybody else's robot!

You need to remember that the only "stupid"
question is the one that is not asked. If the
responders wish to demonstrate the maturation
level by denigrating your question that is their
problem.

That said don't ask me the same stupid question
three or four times, listen to the answer the
first time.

I doubt that the difference in resistance between stainless and copper
is going to cause any significant additional losses in a whip antenna.
That difference will be small compared to the other losses. Stainless
is often used for whip antennas because of its mechanical properties.

Max,

I can likely use AltaVista BabelFish to translate the German. I use
BabelFish
to view Japanese ham web-pages.

I took a look at the links. From what I am understanding these are
front-end
regenerative circuits. I guess that what I can do is instead of using a
loop I
could use a broadband coupling transformer, and then place the tank in shunt
with the output of the coupling transformer.

Thing is, I don't understand how the regenerative preamp is different from
the regenerative recever (aka regenerative mixer down to baseband audio).
Can you enlighten me?

Thanks,

The Eternal Squire

Depends on what you plan to be looking at.

For audio, you can probably get away with whatever wire you have around, but
don't try to do any critical measurements.

For RF or digital work, no, you can't homebrew those probes, any more than
you can homebrew the scope itself. An oscilloscope probe is part of a
precision measurement system, and the actual requirements that it must meet,
to pass a complex signal UNDISTORTED IN ANY WAY, are TOUGH.

Last time I bought probes, commodity probes were running around forty bucks
each, new. And worth it. Real Tektronix probes, new, will cost you a LOT
more, and they're worth every penny.

Yes, I've several proprietory s/steel whip antennas that give
excellent results. But a question springs to mind. If a s/steel
antenna has slightly higher resistance, does that appreciably lower
its Q?

Just to make a few things clear, I would like to say.

There is no differents between a frontend and a preamp, it is the same only
thing is the mechanical layout.

The only differents there is between a regenerative reciever and a
regenerative
preamplifier is that the reciever has a detector, the way of function is the
same.

I will scan the 4 pages I have with a Q-multiplying preamp and mail them to
you, so please tell me if the e-mail adress you are using is valid.

you mean it's bandwidth? probably, but why worry? it's not cut to
resonance, anyway. it's a resistor in an E field. Tx units can be run
with the telescoping verticle collapsed and still control the toy at
short ranges. i think the biggest prob would be front end overload
regardless of the antenna, which i'd try to deal with in an active
antenna setup which is well suited to short verticles, you just can't
let it blast the front end of one of those little RC Rxs.

i've used all kinds of different scraps of wire to get FM RXs going to
see if they work. how about those little pieces of scrap wire on RC
cars? they're no better than yours.

BR,
mike

I don't have any figures available but I wouldn't think so. The
difference between the resistance of a 2-foot piece of copper and a
2-foot piece of stainless is going to be pretty small.

Like wise, here.

The DSL comes to the house, goes into a plastic conduit, under the ground, 50' to the lab, into the ADSL modem, out as ethernet to a hub, then one line to the server and one back to the house, where it comes in and goes to two
more hubs and 4 computers.

The The noise is heard as a popping sound in the receivers, and is present in the lab, and in the house. It's worst around 10MHz and 15 MHz, and occurs when there's ethernet traffic. I hope that putting the antenna up on a tower
will help. Right now I SWL with an antenna in the attic.

The server is a large minicomputer, maybe it's not intended for operation in the home, maybe has less EMI restrictions?

For audio? Maybe. For anything higher, definitely not. Good O-
scope probes (thinking Tektronix here) are made with a high degree of
precision, and outstanding quality in materials. This is not something
that can be duplicated at home without investing a small fortune in
specialized manufacturing equipment.

You're far better off picking up some surplus Tektronix probes at
whatever ham swap meet or electronic surplus place is local to you.

The short answer is that stainless probably won't make a noticeable difference in loss, and therefore won't make a significant difference in Q.

The conductor loss of an antenna of a given wavelength size gets less as the frequency gets higher. That's because the antenna length decreases in inverse proportion to the frequency, while the loss per unit length increases only as the square root of the frequency. So for a given wire diameter, a half wavelength dipole at, say, 10 MHz has half the loss of a half wavelength dipole at 2.5 MHz. Stainless steel whips are fine at 2 meters. But an 80 meter dipole made from small or moderate gauge stainless wire could be pretty lossy -- almost certainly so, if the stainless is a magnetic alloy. (Being magnetic greatly increases the RF loss -- by a factor of the square root of the permeability.)

Loss becomes very important when a whip is a lot shorter than a quarter wavelength. However, in many or most cases (like an HF mobile whip), the whip typically has a fairly large diameter where the current is high, and the whip loss is swamped by other losses, so the whip loss isn't objectionable.

It's always possible to come up with a combination of whip diameter, length, and frequency where stainless could be a poor choice -- but it's uncommon in typical applications.

I heartily endorse what the others have said about scope probes. And there is a big difference between Tek probes and commodity probes. A quick Web search shows this is an 80 MHz scope, so a good probe will be necessary if you want to get the most out of it. A lot of Tek probes show up on eBay. They're pretty rugged, so your chances of getting a good one are probably better than for a lot of other electronic equipment. Check your scope's input capacitance, and make sure the probe you get is compatible with it. You should be able to find input C specs for most common probes on the probe manufacturer's web site or elsewhere on the Web. If this is a two-channel scope, it's a very good idea to get two probes of the same type and cord length. You might want an additional probe for the external trigger. This one can be lower quality without having a big impact.

Source record: 33666

For years I've had a relay box in the back yard to remotely switch among antennas. The plastic freezer boxes I used deteriorate in the sun and have to be replaced from time to time. Last time I was at the surplus store I picked up an ammo box which will be the new home for the relays. I plan on using N connectors for the RF due to their weatherproof construction. The problem is a connector for the relay control cable. I want a weatherproof bulkhead connector with at least 8 or 9 conductors, and I'd like the cable part to be weatherproof also. I don't want to use an in-line connector because of the problems of weatherproofing and strain relieving wires going through the box wall.

There are a bunch of old military connectors that would be fine, but I need a set of complete ones, with back shell for the cable end, etc. I've been keeping an eye on eBay, but so far haven't spotted anything quite right.

Does anyone know a source for a suitable connector set?

I'd take a look at the "circular plastic connectors" sold by Digi-Key.
(among others)

They're not inherently weatherproof but some silicon sealant will make
them that way.

That's what's used on the pan/tilt heads that aim the transmit antennas
on TV microwave remote trucks - certainly at least as difficult an
application as what you're doing. The connectors far outlast the drive
gears!

Hey Gang..

I have recently become interested in the 1750 meter band (160-180 khz).I have been searching the net for information,circuits,reports,anything I can find!
I plan on homebrewing a TX/RX pair,once I do a little more research. I have found a few Schematics,and plans for a couple different transmitters,and antenna's,but no plans for recievers. Can anyone help me out? I'd prefer to go the homebrew route,mostly for experience,and for a learning experience.I don't have much experience with RF electronics,and have been working my way into this "grey area/black magic" ;-) I have built a few FM transmitters,amplifiers,etc..
(I'm really proud o the FM amp I built,1 watt from a 6AK5,First RF project I have built from scratch that worked!)

Any schematics,links,suggestions on circuits,antennas,etc,etc would be great!

Thanks a bunch! Patrick.

Make a search for VLF gear, it is for 137 KHz but should be no problem
for redesigning to 160 KHz.

I think you will rarely see a receiver for this band.

There is no, or virtually no, commercially made transmitters for
this frequency and power, so you don't have much choice but to
build. Plus, a transmitter is nice and simple, so you might
as well build it.

But due to the very low allowed power, and the low frequency of
the band (and associated inefficiencies of the antenna), you really
need to go with a good receiver. So I'm sure many would use an
existing receiver that happens to cover the frequency, with it's
good selectivity and features.

If their receiver doesn't cover the band, then they'd add a converter.
I have no idea what's on the web, but there have been a number of converters
for this band described in the magazines over the years.

People building receivers are likely building something really high
performance, maybe moving away from the common receiver schemes in order
to get the most performance for the limited conditions. I'm sure such a
receiver was described in the late Communications Quarterly in an early
issue. Unless you are willing to put in a lot of effort, duplicating
such receivers are not the route.

That said, many converter schematics can be used, so long as
you change the crystal frequency and the front end tuned circuits.
Decades ago, a common LF converter was a single transistor in
a pierce oscillator/mixer combination, and no tuned circuit (or a simple
low pass circuit) at the antenna. Likely not great performance, but
a way to get started and little to go wrong.

And just about any simple receiver design could be used to get
a simple 1750 meter receiver. Pick one with decent selectivy, and
then again modify the local oscillator and front end tuned circuits.

A standard electrical cable gland will weatherproof the cable going through the box wall (or whatever you call that thing with a compressible rubber washer that squeezes down onto the cable). That would leaves an in-line connector pair which is a good shape to wrap with tape, so it needn't be inherently waterproof.

>There are a bunch of old military connectors that would be fine, but I

>Does anyone know a source for a suitable connector set?

There's a fundamental strong repulsive force that pushes matching surplus plugs and sockets to opposite ends of the Universe.

I had some success with mounting a DIN plug and socket inside any old MIL connector shells for waterproofing. The only requirement is that the MIL housings are compatible - I'm presuming that the pin configurations don't match (see above) but that doesn't matter because you strip them all out.

Remove the backshells (cable clamps and water seals) and drill out the insides of the two MIL connectors to accept the two DIN connectors. Then mate the two MIL housings together (still with the backshells removed for access), push the DINs together inside the MIL housings and epoxy each half into its MIL shell. You now have a waterproof DIN connector.

I hope that makes enough sense...

The DIN connectors are OK for relay-type currents.

There was a nice article in the late 60's about buliding a rig for the
"forgotten band." It may have been in Popular Electronics, or Radio and
Electronics.

Is this band still allocated for low power experimental use without a
license?

[thorough-sounding explanation snipped]

Thanks, Roy. Sounds like i should be okay with ss at 40Mhz for this
purpose, then. I've been up to see my supplier in N. London today and
returned with a good selection of various ss spring wire to try out.
I'm given to understand that the rx antenna length isn't that
important with this r/c stuff, so I guess 30-35 inches should be fine.
I'll mount it in a conical well with curved sides as someone else
suggested to minimise any stressing.

If you can find them one of the best sources for the 1750m band was Ken Cornell's "The Low & Medium Frequency Radio
Scrapbook". There were 4 editions, that I know of, from 1975 to 1982. They were a collection of circuits from everyone
that was experimenting at the time. Ken has long become a 'silent key' and so there hasn't been a new edition out in a
long time. Check around, you might find some available, they're well worth having.

"Transmitter for the Neglected Band" and "Tuner for the Neglected Band", both written by Jim White/W5LET, were in the Jan and Feb 72 editions of Popular Electronics, respectively. You can probably find those issues on film at your local public library. Both are tube projects. The tuner (receiver) is some kind of funky TRF/superhet hybrid, and is tuned by adjusting four compression trimmers (IOW, the tuning is virtually fixed).

>Is this band still allocated for low power experimental use without a
>license?

Yep, limited to 1 watt power input to the final, and the total antenna/ground system is limited to 50 feet.

You can get information about copyrights at http://www.uspto.gov. There's no doubt that the original copyright is still in force, since the term of a copyright is much longer than 30 years. (They've changed it recently -- I think it was from 75 to 125 years, under the urging of Disney, whose early copyrights were expiring.) Unless sold, a copyright owned by an individual becomes part of a deceased's estate, so if the author held the original copyright, it's probably owned by the author's heirs. If it was held by Ham Radio magazine, it might be owned by CQ, who took over Communications Quarterly, the successor to Ham Radio; or the ARRL, who took Communications Quarterly over from CQ. Or possibly Craig Clark, who bought the Ham Radio Bookstore from Ham Radio years ago. Or, the author might have had an agreement with the publisher to have the copyright revert back to him from the publisher after some period, in which case the heirs have it.

Of course, you can copy small portions for various uses under the "fair use" doctrine. But copying the whole thing would almost certainly be a copyright violation.

If you're really interested, I'd recommend seeing a qualified attorney before you proceed. I'm not one, and what I say shouldn't be taken as legal advice.

Yes, the Transmit is limited to that power and antenna. However, the Rx is not and I'd use a fairly large antenna or tuned antenna loop with a FET follower at these frequencies.

For the rest of the Rx, a converter is a good way to go and the FET will give a low enough output impedance for a regular mixer of some sort.

I've played around on this band for a few year now, and I've noticed a few
things. It doesn't seem to matter what receiver you use because the noise on the
band is almost always much higher than the receiver's front-end noise. Increase
the receiver's sensitivity and you increase the noise. Instead, work on the
receiver's selectivity. Or send the audio output from the receiver into your
computer's sound card and use one of those great FFT programs designed for
weak-signal work. Do that and you can see signals well below the noise floor.

As far as antennas are concerned, loops are popular but there are plenty of
other options. Remember that the band is for experimentation, and part of the
fun comes from experimenting with different antennas. But even with all the
noise on the band, you can still work 20+ miles CW with nothing more than a wire
in the tree and any old receiver that will tune the band.

Paul, it sounds like you need to get yourself a CPC catalogue,
pdq. It is similar to RS/Farnell, but the product range is more
aligned to your specific needs.

eg, In the Aerial section there are standard flexible and
super-flexible whip aerials, for cars. Wideband AM-FM reception,
complete with adjustable mounting block and output cable+plug.
About 340mm long on avg. Prices range from ï¿½2:92, to a horrific
ï¿¼4:86.

Note also that CPC does a range of build-it-yourself kits. eg,
Part number HK00224 is a wideband antenna amplifier kit. Metal
cased (24x36x86mm), with 22dB of gain over the range 10-150MHz.
Price is a bank-breaking ï¿½7:49.

See <http://www.cpc.co.uk> or 08701 202530 for a printed
catalogue or CDROM. Farnell own CPC, so if you have a
Farnell account you also automatically have a CPC account.

I presume you are operating at 35 MHz or so? So your losses in a 30"
whip are already rather high, especially into a typical RC Rx
front-end, so the material will not count for much either way.

A number of emergency beacons use a very robust antenna made from 3-4
laminations of stainless steel tape, something a little like the tape
in your retracting tape measure. That would be worth looking at. I
have seen such beacons/antennas survive and operate after severe, and
fatal, A/C crashes.

Ah, that's the one. I remember it well. With the plethora of digital radios
that tune down to 150 kHz these days, the rx wouldn't even be a
consideration.

Here's what I don't understand about copyright law. If a hobbyist wants to
photocopy out of print work for his own use, or even to redistibute to
others with like interests, how is it a copyright violation unless he
either profits from it, or deprives the legal owner of the copyright from
profit?

I understand the concept - I just don't understand the way the law is
applied these days.

It probably being a FM dual band (handheld) transceiver , by increasing the
mic gain ,you'll also will increase the deviation .
Is that really what you want to do ?

Need to apply the "Reasonable Man" theory. If it would be reasonable for the copyright holder to profit, then he has been damaged. A copy, distributed to a limited audience, for scientific use probably would fall under a "fair use" exception. A "I have found this wonderful item, and here it is" distributed to persons who would have purchased the item had it not been distributed would be infringement. The subtle differences is why we have courts, and a legal system.

Every once in a while I point out what the copyright or patent law says. I almost always get responses from people who feel they should be able to do something other than the law states -- for example, a lot of people feel that they should be able to build a patented item for their own personal use, while the law specifically forbids it. Or photocopy a book that's out of print. And so forth. I think most people don't really want to know what the law says -- they'd rather keep their notion of what they think it should say.

I don't make the laws. I don't enforce them. And, shoot, I'm not even qualified to say what they are or what they mean. Anyone really interested in learning what the laws say can go to http://www.uspto.gov or a bunch of other authoritative sources. Better yet, see a qualified attorney, who can also tell you how they're enforced. Then do whatever it is your conscience (or rationalization) lets you do. Most people are probably going to do what they want anyway, no matter what the laws say, and come with reasons to justify it.

Want to know why the law says what it does? Ask your congressperson. Have a complaint? Tell your congressperson. But be warned -- people who like sausages or have respect for the law shouldn't look too closely at how either is made. And it ain't pretty.

Frequency limits prevent slot antennas in plate metal armor?

If so, loop antenna on top of the polycarb, with another
layer on top of that? You need a certain amount of standoff;
how much at your allowed frequencies? It'll amount to a box
or block of plastic stuck on the 'bot, but should be
relatively invulnerable.

I couldn't read the number on mine at first, either. The IC body
was grey, and the lettering was only somewhat darker grey. There
was also some wax or something on the IC. My first thought was that
there was no part number on the IC.

But since I knew there was no ceramic filter in there, I also knew
that it had to use some odd scheme. It was only after I found a likely
IC that I could see that the IC number actually matched it.

Check with Allied Electronics. They carry a large stock of Amphenol connectors like those used in military applications. You might also consider just installing a terminal strip inside the switch housing and running the cable directly into it rather than using an expensive connector. You can easily waterproof the entry point with a rubber feed thru bushing or silicone sealant.

I'm pretty disappointed at the amount of flame this posting generated.

Allen asked about interfacing, I assume the question was about interfacing. OK, he said newbie, unfortunately, he didn't say newbie to amateur radio, PICs, or putting them together.

As someone pointed out, the 100 - 300 mile range is a bit of a push. On VHF, that's going to take an unrealistically high antenna, no getting around that unless you have a repeater or satellite. 100-300 isn't a bad 80 meter range, but 80 means huge antennas, probably not reasonable for the sort of robot I would picture, but he didn't give us a lot of insight into his application. Also, in the summer during the day, it's going to take a buch of power. Tough to see a robot carrying that much battery.

Just a note to other new posters ... a lot of times folks give a narrow question in the hope that the conversation won't go too far afield and they'll get an answer to their question. The problem is that us old farts know that there are a million ways to do anything. If you have some insight into the application, it gives us a shot at narrowing down the alternatives.

OK, now, about interfacing to the rig. As always, it depends.

There are 3 things you want to do with a rig - send, receive, and switch between the two.

Switching between the 2 is often the messiest. Different rigs have different ways of doing this, but in most cases, a relay is the most direct. A PIC will drive one of those little DIP relays directly. If you don't want the mechanical bit, a transistor or two, or perhaps an open collector buffer like a 7407 will protect the PIC from the voltage on the TR line, which in most modern rigs is in the 8-10 volt range. Tube rigs are obviously different, but I can't picture a robot running around with a Henry 2K on it's back!

Receiving is simple, wire the headphone jack directly to the PIC, maybe a little resistor in there. The PIC is plenty fast enough to decode the audio. If you're a bit of a wuss about the software, maybe you bring the audio into a 567 or NJM2211 and go into the PIC with a decoded digital signal.

Transmitting is a bit messier. Some rigs like the Icom 706 have an FSK input that allows you to shift the modulation frequency with a simple digital signal. Most rigs, however, you will probably go into with audio. There are 2 issues here. First, the level has to be carefully set for the rig. This isn't so hard, it's just a couple of resistors, but it takes some fiddling to get it right.

Secondly the shape of the waveform is an issue. It's real easy to generate square waves from the PIC, but in most cases, these will generate lots of spurious output. Depending on the application and the sort of encoding you will use, you will need to come up with nice sine waves. There really are 3 ways to do this ... in many applications you can simply get away with a good low pass filter between the PIC and the radio. This will take a bunch of tweaking, though, and you will need a good scope, and preferably a spectrum analyzer to get it right. You can also generate the sine wave by having the PIC output the sine wave using pulse width modulation and a little filtering. In my experience, you can get extremely good sine waves this way, BUT the PIC is 100% dedicated to the task, which means your data rates will need to be low. The third approach is to build an oscillator that you can control with the PIC. Given that you will probably need only two frequencies, this may not be such a bad approach.

Actually getting into the rig is generally pretty simple. Most Icom rigs have the audio on the mic jack, which is typically a RJ-45, so it's pretty simple to do the whole thing through the RJ-45. For some, though, you will need to put the audio into the mic, and get it from the headphone jack. Of course, some radios have an accessory jack on the back with everything you may need. Generally, these are some sort of unusual jack. Icom likes 13 pin DINs, which are available, but you won't find fistfuls of them at your local Best Buy. If your radio uses one of those 4, 6 or 8 pin round connectors with the screw on ring around them, you can ofetn get them at a CB shop.

Hope this helps ..

..

Don,

Minicircuits has a reputation for selling small quantities directly to hams.
I've bougtht their kits directly and single quantities from one of their
distributors.

If you don't need the low frequency response of the SRA-6, you can get some
of their mixers from Down East Microwave.

Their web page is at: http://www.downeastmicrowave.com/

> hello,
> I need a varaible 490-510 uH coil. any sugestions on making it at
> home, or beter step by step directions.

I'll assume this is a serious question...

That's such a small range, only 20uH out of 500 or about 4%, that it should be easy to get the desired variability. In fact, the most difficult part may be trimming the coil to the correct value in the environment where it will be used. You didn't mention what Q you need, or what frequency range it will be used for, or how much power it should handle, or whether you want to vary it often or just set-and-forget. Those factors make some difference with respect to the "best" solution to your question.

If you don't mind it being fairly large, you can wind about 100 turns of 32AWG wire on a 2" diameter form, taking up about an inch of length, and make it variable by putting a couple of powdered-iron toroids on a Nylon screw in the middle of the coil, with the screw arranged so you can move the toroids in and out. That will probably give you a bit more inductance than you want, and you can remove turns until the value is as you need. You can vary the number and size of toroids you use to change the tuning rate. Other diameters, lengths, etc., are possible, too, of course: just use one of the standard inductance formulas to get close and trim as needed. (Homebrewing is often about using materials already on hand.)

Another possibility is to use a tuneable potcore...but you may have difficulty finding the core. You may be able to simply wind the wire on a powdered iron or ferrite toroid and adjust by taking off turns and/or squeezing/stretching the turns, if it's set-and-forget. Another idea is to simply buy a coil whose adjustment range includes the values you need--see DigiKey or Mouser. There are several other solutions. You very likely do NOT want a roller inductor!

Cheers,
Tom

892. HP 6129C 6130C Digital Voltage Source Supplies

Source record: 33609

I have a couple of these power supplies -- nice old HP vintage -- couldn't figure out why, with the same binary code, one would give a negative voltage, others it would be positive -- the secret is in the jumper W on Board A2 -- this sets the "sign" signal for the DAC circuitry.

By using two supplies, one with A2 W Jumper at "A", the other with A2 jumper at "B" you need only one programmer to yield positive output from one supply and an equal negative voltage on the other -- nice for testing amplifiers.

For $19 the HP6129C (+/- 50VDC, 5 amps) is a real bargain.

894. Re: scope probes

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-08-05 18:58:13 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vivvi6c7dqc477@corp.supernews.com>
Source record: 33611

From a brief look at the referenced web site, it looks like the author did a decent job of making a low impedance probe. It should work quite well if carefully constructed.

But it's actually a lot easier to make a good 50 - 1000 ohm probe (which the web site describes) than a 10 meg probe. A 10 meg, 10X probe is a lot more useful for most everyday measurements, which is why it's universally used on scopes up to several hundred MHz. At least as important as the high resistance is the relatively low capacitance it presents to the measured circuit. (A good low Z probe has considerably less capacitance yet, so it's a better choice at really high frequencies. It's also fine for probing in 50 ohm environments.)

Making a good 10 meg probe is quite an art as well as a science. If you ever disassemble an old Tek probe, one of the first things you'll notice is the coax. It's specially made with a resistive center conductor to damp reflections, and lossy dielectric to reduce piezoelectric and triboelectric effects. (If you don't know what these are, connect a piece of regular RG-58 to your scope input, turn the sensitivity up, and flex it or rap it with a mallet.) Another tough problem is "hook", a nonlinear property of many capacitors, dielectrics like PC board material, and even resistors. This creates funny, hook-shaped step responses (which is how it got its name), that are difficult or impossible to compensate. You probably won't see hook at 50 ohm levels, but it's pervasive in high impedance environments. The little circuit board in the scope compensation box is likely a specially-made low-hook expoxy glass formulation, or an inherently low-hook dielectric like polysulfone. And both the capacitors and resistors were carefully chosen and specified for low hook and other nonlinear properties.

A cheap or homebrew 10 meg probe is fine if you don't really care if what you see on the scope looks like the real signal. Or if the amplitude of a sine wave is really what the scope says it is. But if you do, you need a decent probe.

The TV-V7A is a 50 watt mobile rig. However the same comment on mic gain would probably apply. Perhaps talking a little closer to the mic might help. Or perhaps there's a problem with the radio that needs to be taken care of by a repair person.

897. Automatic RF noise cancellation and audio noise measurement

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-08-05 22:12:22 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0308051412.54d4c913@posting.google.com>
Source record: 33613
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna,comp.dsp,sci.electronics.design,sci.electronics

THE BIG QUESTION: How do you measure the audio noise level in a receiver? Does anyone here know of any circuits that show the overall audio noise level?

Let me tell you what this is all about.

SIDE NOTE: Thanks again to those of you who helped me with the SWR/wattmeter project I worked on last semester. This project taught me more about ferrite cores, op amps, and diodes than ANY class possibly could. I learned about stray capacitance and what rails mean. I also learned that not all 1N34A diodes are alike.

In this coming semester, I will be working on an even more ambitious project - an automatic noise canceller for 160m to 10m. It will definitely be a control system, and it may even use DSP. The device will also require a motor for automatically adjusting the controls. The idea is to design and build an automatic version of the Timewave ANC-4 or the MFJ-1025/1026 RF noise cancellers.

The ANC-4 and MFJ-1025/1026 are manual devices. There are automatic noise cancellation devices, but their adjustments are at the audio level rather than the RF level.

The back panel of my device will contain:
1. Connector for the signal antenna
2. Connector for the transceiver
3. Connector for the noise antenna
4. DC power connector

The front panel of my device will contain:
1. Power switch and the obligatory idiot light to show that the power is on
2. 2 audio connectors: one connects to the transceiver, and the other connects to an external speaker
3. Frequency range control for choosing the inductance values, as the proper inductance values in the RF noise cancelling circuit varies with frequency
4. Phase range knob so that the phase shifter can cover all 360 degrees
5. Manual noise phase knob
6. Manual noise gain knob
7. LED display to show the noise level
8. Noise phase adjustment push-button: Pressing this button activates the control system to adjust the phase shift of the noise.
9. Noise gain adjustment button: Pressing this button activates the

control system to adjust the gain of the noise.

Other features:
1. I need to design my automatic noise canceller so that parts won't blow up if I transmit 100W through it. This probably requires some type of automatic bypass circuitry.
2. Transmitted power must not reach the noise antenna (at least not without a great deal of attenuation)
3. It also needs a low insertion loss.
4. A preamplifier would be desirable.

How it would work:
1. You manually turn the phase and gain controls to the minimum settings. (Or I could put in a reset button to do that. No, that would add too much complexity to the circuit.)
2. You select the band using the band inductance switch.
3. You move the phase polarity switch to the negative setting. If the noise cancellation procedure does not work, it probably means the opposite setting is required.
4. Press the noise gain adjustment button. The device adjusts the noise gain until a change in the signal level (or the S meter) is just noted. (Some type of derivative function would come into play.)
5. Press the noise phase adjustment button. The device adjusts the noise phase shift so as to produce a null in the signal level (or the S meter).
6. Steps 4 and 5 could be repeated to make further adjustments. There might be away to activate the control system with just one button.

Does anyone know of circuits that measure audio noise? Making the RF noise canceller automatic requires an audio circuit to monitor the noise level. This noise level needs to be converted into a large DC voltage, which feeds the motors that turn the variable capacitor and potentiometer.

Hi Roy,
Some excellent points there! A high impedance probe is, of course, a useful part of the test and measurement arsenal. However, it's worth remembering that at frequencies above about 16MHz, a 10Meg probe, which typically has about 10pF input capacitance, will present a lower impedance to the device under test than the 1000 ohm design described on the website. (The 1000 ohm passive probe has, as you point out, much less capacitance.) If, like me, you look at a lot of high speed digital signals, the passive probe is very useful and your choice of probe may depend on what your definition of an 'everyday measurement' is. So, I may have to politely disagree on the 'universally used on scopes up to several hundred MHz' bit of your post! I think the passive probe provides better signal integrity, even out-performing active probes at very high frequencies. Whatever else, Roy, we're both agreed that a bad 10 Meg probe can be worse than useless! You end up chasing stuff which is an artifact of the probe.
best regards, Syms.

p.s. For those interested, try http://www.sigcon.com/ , click on archive, read the article 'Probing High-Speed Digital Designs' near the bottom of the page. Although it says digital in the title, the article is appropriate to this thread IMO. Also, http://www.emcesd.com/pdf/cd94scr.pdf is worth a read.

Last I looked at that issue the tone (beep) was generated by the CPU
and feed into the audio circuit via a fixed value resistor. No
adjustment except for changing out the resistor to some other value
was possible. You might call Icom America to see if they ever had
investigated it further. While I was there were no service issues
concerning the beep other than it being loud for some users.

I've done a fair amount of playing around with PIC16F876's. They
have two built in PWM generators. You set the overall carrier
frequency by writing to a register and then control duty cycle as
you need it. Turns out to be very low overhead.

Hope this helps.

Allow me to infuse a different idea. Think about noise as a fairly broadband phenomenon. The same atmospheric noise that you hear on 21.500 Mhz will also be heard on 21.510 Mhz. Consider the possibility of biulding two identical receivers, the main receiver tuned to the desired reception frequency, the other tuned just a few Khz away, but out of the received signal's bandwidth. Then, you detect the noise on the second receiver, invert it, and sum it into the first receiver's signal chain. This concept is used in ultra-low noise, high sensitivity deep space receivers to almost

totally eliminate noise in the received signal.

Now, as to your concern to keep 100W of RF from blowing up your noise canceller. That's what antenna changeover relays are for. They normally connect the antenna to the receiver, but when the transmitter is keyed up, the relay connects the antenna to the transmitter output, and disconnects it from the receiver. Simple, but effective, and has been used for many many years in amateur as well as commercial radio equipment.

I wasn't able to find such a thing in the (quite elaborate) electrical department of a large DIY store. Is this something used in electrical mains wiring (which is what the DIY store carries), or for some other purpose?

In this country, it's long been standard practice to bring mains power into a house via a "weather head", which is a pipe bent into a U shape, so the wires enter it upward. There's a rubber grommet for the three large diameter mains wires built in. This is very effective for its intended use, but not useful for my purpose. I've never seen modern electrical wiring run directly through an outside wall, if that's the function of the "gland".

I'll try looking at a large electronics store next time I'm there.

There are numerous sources of noise at the input to a receiver:

1) Background HF noise that exhibits a 1/f rolloff characteristic. This has seasonal and diurnal variations.

2) Atmospheric noise caused by local or near local weather. Remember there are 10,000 thunderstorms in the world at any time.

3) Solar flare noise. During an solar X-ray event the HF noise, #1, can increase by over 60 dB for short periods of time.

4) Local line interference noise.

5) In the future, BPL noise.

6) I'm sure there are other noise sources such as defective insulators on power lines. ;-)

The ANC-4 and MFJ 1025/1026 ONLY operate on #4.

So, your first task is to become familiar with the spectral characteristics of each so you can design a basic filtering circuit for the undesired noise source. My ANC-4 does not respond to the 1/f HF solar noise sources, atmospheric induced noise or solar flare noise.

Weather induced noise contains frequency components that are in the audio passband, you can hear lightning induced static crashes in your SSB/AM radio. How will you discriminate between desired audio and static audio?

Solar flare noise sounds like a slowly rising rushing hiss in the receiver. It has a slow rise time generally in the range of tens of seconds to minutes. It is broadbanded and will easily over ride any low level desired signal. The noise to signal, NOT signal to noise, ratio can easily exceed 40 dB making detection almost impossible. These characteristics are proportional to the intensity of the solar flux and also the wavelength of the solar flux. Detecting desired signals in this environment is extraordinarily difficult.

Manmade noise, these are processed by the ANC-4 and MFJ units, contains basically repetitive waveforms from TVs, VCRs, Remotes, Routers, Computers, etc.

A design approach would be to use digital filtering and a series of Kalman filters [digital filter algorithms], assuming they are available to the general public. The Kalman filters would be tailored to the spectral content of the noise source you are attempting to cancel. A

second design approach would be a fast Fourier transform that discriminates N/S from S/N. You want to keep the noise OUT of the FIRST RF STAGE to avoid pumping the AGC and getting false signals. For HF digital filtering this will require a very fast processor [possibly GHz range]

How to measure the AF noise from a receiver? I'd start by looking into a Bolometer circuit with AC coupling. This would give a pseudo RMS reading that could be used as a reference for a series of servo based op-amps to control your gain and phase circuits.

Depending on how far you want to pursue the science it could be a very interesting project.

With a statement of principles it is YOUR Project, NOT the project for the members of this list. So, go and have fun!

Jason:

Very similar to what you are describing is popularly known as a "Noise Blanker" Motorola introduced their design for mobile radios in 1959 as an "Extender" In the same time frame, Collins offered a model for the S-Line and KWM-2. I designed a tube model for GE's Progress Line radios, and I forget who designed the solid state version. The concept has been described in numerous places, so do a bibliographic search of Engineering Index, or Scientific Abstracts, or whatever that school has access to. You also need to familiarize yourself with the concepts involved in noise balanced squelch, which was patented by Motorola back in the late 30s or early 40s. It will tell you how to do the audio noise level measurement meaningfully and apply it usefully.

It seems the data sheet is in error concerning the IF. they spec it at
70khz. But if you reverse engineer the front end and VCO LC network
the VCO is 10.7Mhz lower than the rf input. I figure taking out the
varactor diode and dropping in a 120pf mica I can get it down to
30mhz, then for AFC use a 4pf varactor diode to compensate for temp
drifting. I snapped up a few of these and they're pretty much the
same, too cheap for a ceramic filter other than disc caps. And with
the 10Ghz contest coming up I might just make a few contacts.

You can figure if 3 volts is 30% then 10 volts will be 100%. But make sure you keep an 8 ohm load on the audio amp. The amp would be operating way out in the nonlinear portion without 8 ohm load, the result would be distortion. Figure your'e going to need 1.2 watts and up to 12 watts of audio. Depending on how loud you want it on the Rx end.

These things have GOT to exist in the USA, but clearly the name is
different.

They are used with metal conduit-and-box wiring systems, wherever you
want to bring a flexible cable out through the wall of a conduit box
with better waterproofing than a plain grommet.

Go to www.farnell.com/uk and search for part # 3034367 - click for
details and this should give a reasonable picture.

The outside of the fixed part looks rather like a through-bulkhead
double female N connector. It goes through the box wall, with some kind
of O-ring seal, and is fixed with a single large nut. The cable threads
through the inside, and is sealed by a rubber ring and a screw-down cap.
Result - a completely waterproof lead-through.

All together now: "Oh, ya mean a [Fill In The Blank] - why didn't ya
say so?"

Anyway, the whole point was that these [FITB] things are available in
cheap plastic, and are ideal for getting cables through the walls of
plastic or metal boxes in a totally waterproof way. You can install
in-line connectors on the 'tails' of cable if necessary, and they make a
very easy shape to wrap with waterproofing tape.

This is vastly better than installing chassis-mount connectors on the
box wall, and then trying to wrap tape onto a very difficult shape.

Hi Jason:

I think the "signal antenna" and "noise antenna" are both just antennas. I can't see how you can make an antenna that only hears noise and another that hears the same noise and signal. If that's the case then by adjusting the relative phase and amplitude of the two "antennas" what you are doing is changing the antenna pattern. This will improve the overall s/n if there is a source of noise that's coming form some direction more than from everywhere.

In "Beam and null switch step steerable antenna system" U.S. patent <http://www.delphion.com/> 4,063,250 <http://www.delphion.com/details?&pn=US04063250__> Fenwick has an antenna system where the main lobe is steered using time delay beam steering (this is a frequency independent version of a phased array) and in addition can steer a null independent of the main lobe. He used mechanical relays and coax line, but a more modern version could use PIN diodes and a computer to try all the possible main and null lobe possibilities and use the best ones.

To measure the sensivity of an AM receiver you measure the RMS audio output voltage with a signal present and without a signal present. For a more detailed look at the noise you need a spectrum analyzer, like the HP-Agilent 4395A that can make true RMS noise measurements, see: http://www.pacificsites.com/~brooke/4395A.shtml

Have Fun,

Brooke Clarke, N6GCE

Hi Jason

Theres a whole lot of unworkable ideas on this thread. I shouldnt rush in without reading up well first.

I'll just address a couple of Dave's ideas.

Dave Shrader <david.shrader@comcast.net> wrote

> Weather induced noise contains frequency components that are in the
> audio passband, you can hear lightning induced static crashes in your
> SSB/AM radio. How will you discriminate between desired audio and static
> audio?

Lot of work was done on this in the 30s, the cnoclusion was they couldnt. However you can if you use the standard 405-line TV noise reduction method. Basically detect brief signals that are greater in amplitude than your wanted a.f., and zero or reduce the af output during that time.

> A design approach would be to use digital filtering and a series of

> discriminates N/S from S/N. You want to keep the noise OUT of the FIRST
> RF STAGE to avoid pumping the AGC and getting false signals.

I dont see how you can manipulate signals that havent even reached the first rf amp. You cant even read them as theyre microvolts. Putting them thru any kind of digital filter - you work it out.

Jason your idea of mixing different noise sources is also a non runner. Sorry, but youve got to consider _exactly_ what is in those noise sources and how they differ. It will soon become apparent that by the time you add them youve got 2 different things. The noise f distribution might be the same, but the noise signal will be quite different.

Regards, NT

Thanks for the reference. The closest thing I found to that was something roughly similar for what we call Romex wire -- flattish, vinyl insulated three-conductor (called two conductor with ground) wire used for house wiring. I'm not sure it was weatherproof, though. It would be harder to seal something of that shape than it would to seal something round.

I suspect that the part you referenced is uncommon here because of the larger gauge of our house wiring due to the lower distribution voltage. Wire smaller than AWG14 (SWG15) isn't used except for lamp and appliance cords and the like, never for fixed wiring. The AWG14 or 12 wire used for house wiring is virtually always in flat Romex cable. (Four conductor 220 volt wire is round but large diameter.) Interior wiring is secured to boxes with clamps which are definitely not weatherproof. Exterior wiring is virtually always in conduit between boxes. I found a number of weatherproof clamp-type fittings for conduit, with similar construction to the Farnell part, but the inner diameter is much too large for the small cable I'll be using. It's been a long time since I looked carefully at the code, but I'd be very surprised if exterior wiring is permitted outside of conduit under any circumstances.

Maybe I should just send my 42p to Farnell. . . Hm, better yet, there's a cottage in Wales we've been told needs beta testing, so maybe we can kill two birds with one stone. . .

I'll check the electronics store. Maybe someone imports them and sells them for other applications.

>up to 12 watts of audio. Depending on how loud you want it on the Rx
>end.

In practice, with a solid state amp it is simply a case of
however much voltage it *can* produce, it *will*. The power it
delivers then depends on the load, and the lower the impedance
of the load, the more current will flow at any given voltage and
therefore the more power will be delivered. The distortion at 3
volts is not going to be significantly different whether that
power is 1/10 watt or 100 watts, assuming the amplifier was
designed to deliver 100 watts.

Which means that with an input impedance of 70k Ohms, the
only question is whether a given amplifier can deliver 10 volts
of audio, even with a high impedance load. Clearly if the audio
amp was designed to drive an 8 Ohm load, then it would
necessarily have to be able to deliver 12.5 watts in order to
generate 10 volts. Hence any amp which can deliver 12.5 or more
watts into an 8 Ohm load should be able to drive the input.
However, if the input to the sig gen is 70K, only a mere
fraction of anything like 12.2 watts is going to be actually
used.

On the other hand, if an amplifier rated to deliver only 2 watts
into 20 Ohms is used... that too will deliver 10 volts, also at
a miniscule power level into a 70K Ohm load, and work just fine.

Note that the actual output impedance of the amplifier in any
case is very likely to be much less than 1/10th of an Ohm.

Also note that the actual power necessary is .00014 watts, and
if the output impedance of the amp or it's rated load impedance,
is actually 70,000 Ohms, that would be the power requirement of
the amplifier too. That also says that an impedance matching
transformer could be used to increase the voltage available.
Hence an amplifier that can deliver 1 milliwatt into 600 ohms
could have a 1000 to 1 turns ratio transformer to boost the
output voltage, and when the output is cranked down about 20 dB,

the output would be just about right.

That happens to be interesting in this case, because many small amplifiers are rated at something just over 0 dBm output into 600 ohms, and that is a fairly loud tone if supplied to a 600 ohm headset (or telephone set, for example). To match such an amplifier to the sig gen input, any transformer from about 100:1 to 1000:1 turns ratio would do the trick, with the former requiring a bit more than 0 dBm output from the amp, and the 1000:1 requiring the ability to crank it back by at least 20 dB.

The typical "line output" of most stereo system pre-amps, tuners, and whatever, is 0 dBm into 600 Ohms. And a 500:1 turns ratio transformer would be just about right to give the volume control a comfortable range. (That is a 22:1 impedance range, so it would be a 600 Ohm to 13K Ohm transformer. Common bridging transformers can be found that match 600 Ohms to 10-20K, and any of them should do fine.)

As to the RF output of the sig generator, it makes little to no difference. You could no doubt short the output and go on a two week vacation without concern that the short is going to cause a problem. The same is true with leaving it with no termination. The sig gen may in fact melt down in that two weeks, but it has nothing to do with the output being terminated or not.

In fact the impedance probably varies all over the universe. You can just attach a short wire to it and see if that provides the range you need. If it doesn't, add a little more wire, or run it more in the direction of the area where it is weak. What you don't want to do is have too much antenna, because if it can be heard in the neighbor's house, they might or might not appreciate it. Keep it down to the minimum that will accomplish what you need.

> front-end, so the material will not count for much either way.

In the CPC catalogue there is a loaded whip antenna (AR71694),
intended for mobile use, where the whip is made from what they
describe as 17/7ph milspec stainless steel. It comes complete
with all fittings, and cable with 50 ohm connectors both ends.
They give the following spec;

Bandwidth: 26-28MHz (which is the UK's CB band).
Antenna Type: 5/8 Wave.
Impedance: 50 ohm.
SWR: Less than 1:1.5.
Whip Length: 1.35m.

Is it practical to think of cutting the whip shorter for
operation at 40MHz, and (even better) is it possible to
predict exactly how much has to be cut off the whip?

How about cannon connectors? or if you are looking just to have the
cable entrance water tight and not removable then look at thomas &
bettes they make all sorts of sizes of water proof box entry fittings.
If not too many pins Hubble makes marine grade plugs and receptacles.

Remember the cardinal rules of waterproofing switch/relay boxes, vis
use good quality connectors
carefully waterproof all connector in/outs
seal box with appropriate rated sealant

and, lastly, drill a small hole in the bottom of the box for water to drain out....

Wasn't this the basis of the TNS?

If so, it worked on impulse noise above the slow AGC level.

The ANC-4 doesn't even let the noise into the first RF stage!!

Not quite the same, but perhaps usable are the split gromets. See
MSC's on line catalog http://www.mscdirect.com at page 3643, or search
for "split cable entry system" using their site search engine.

Or, you could use a standard cable entry boot from Andrew
http://216.91.65.4/pdfs/andrew/221213.pdf

Why not just wind a fixed coil (on a toroid, for example) and tune it
with a variable capacitor (mechanical or varicap)? That's probably a
lot easier than making an appropriate variable inductor. You only
need about 10pF of variability to get the same tuning range (assuming
it's for 455kHz). You should be able to find powdered iron (or
ferrite) toroid info on the web.

Cheers,
Tom

Just use the primary of a IF can. Most already have the resonating cap built in to the bottom of the can. If it's for 455 KHz, and you don't have any, send me a snail mail address and I'll send you a couple.

Ideally you point the noise antenna at the noise, and the signal antenna at the signal. In the real world the noise antenna is usually fixed, but might be pointed at something like a power line. In any case, the noise antenna is usually quite low, and you hope it won't pick up much of the desired signal.

BTW, way back when, either Radio Shack or Lafayette sold a CB radio that used a separate noise channel that was tuned to just outside the CB band. No idea how well it worked.

Hi Jason:

I think the "signal antenna" and "noise antenna" are both just antennas. I can't see how you can make an antenna that only hears noise and another that hears the same noise and signal.

That looks like a common "liquid tight" bushing used to run a
flexible cable from an outdoor electrical box to a piece of machinery,
or an outdoor light using SJ or SJ-T type rubber jacketed cable. They
are available in plastic or machined aluminum from most electrical
distributors.

The line from the change-over relay to the receiver should be shorted
when the receiver is disconnected and either short or a half wave, or
else open when the receiver is disconnected and a quarter wave long.

Well considering that P=E*E/R then 10*10/20 equals 5 watts in my book. Audio amps generally have 10% THD as a rule of thumb, at 8 ohms. And an amp that is rated for 5 watts at 8 ohms won't deliver 5 watts into 20 ohms. And that's because the Vcc doesn't go up when you put 20 ohms on. The Vcc stays the same.So if you put 20 ohms on a 12.5 watt amp rated for 8 ohms, it will draw only 5 watts of power at full blast.

Believe me I've subbed out 16 ohm speakers for 8 ohm, not only does the power drop but the distortion goes way up to the point that it would give you a headache.

Buy 2- 6 .3 volt ~1 amp filament transformers. Use one to supply the 6.3 V filament voltage then hook the 6.3 volt winding of the other to the 6.3 volt filament line and get your 125 volts on the former primary of the other. Works like a champ.

It's also the same scheme widely used for years in VHF FM mobile receivers.
There is a completly separate receiver that receives the noise which is inverted and
applied out of phase to the signal channel to cancel the noise pulses received through the
receiver. The scheme obviously works much better with pulse type noise.

Did anyone have a different book? You didn't even discuss that
in your previous article, and that was well established in my
response.

>Audio amps generally have 10% THD as a rule of thumb, at 8 ohms.

And interesting statement, but not at all true. Still, it hasn't
got anything at all to do with this discussion.

> And
>an amp that is rated for 5 watts at 8 ohms won't deliver 5 watts into
>20 ohms.

That is true, as I carefully explained in the article you have replied
to, though you did not quote the text which explained why that is true.

What you said previously was:

"sure you keep an 8 ohm load on the audio amp. The amp would
be operating way out in the nonlinear portion without 8 ohm
load, the result would be distortion. Figure your'e going to
need 1.2 watts and up to 12 watts of audio. Depending on how
loud you want it on the Rx end."

And I noted that is not true.

Solid state audio amplifiers do not need a specific load for
linearity. The common limitation is that if the load impedance
is too low, at the maximum output voltage there will be
excessive current flow which can damage the amplifier. On the
other hand, if there is a higher load impedance, the *same*
maximum voltage is reached, but less current flows and therefore
less power is delivered and there is *no* significant change in
the operating characteristics of the amplifier. It just delivers
less power.

> And that's because the Vcc doesn't go up when you put 20 ohms
>on. The Vcc stays the same.

Which is why I pointed that out in the article you are
responding to, but have not quoted. The *voltage* still has the
same range, but since the load impedance is 2.5 time higher, the
current will be necessarily 2.5 times lower, and thus the power
delivered is lower too.

>So if you put 20 ohms on a 12.5 watt amp
>rated for 8 ohms, it will draw only 5 watts of power at full blast.

That is exactly the case. However, you've missed the point.
Nobody is concerned about *power* in this discussion, as the
requirement was for *voltage*. 10 volts, to be exact. The
question there for is can any given amplifier deliver 10 volts.
And what was shown is that if the amplifier is rated to provide
12.5 watts into 8 ohms that does tell us that it *must* be
providing, at peak output,

P = E*E/R

as you said, which is

12.5 = E*E/8

which can be solve for E to be

```
-----------
E = _ / 100
\/
```

Or precisely 10 volts. You can draw the conclusion that such an
amplifier will be able to deliver 10 volts. You can also
conclude that if an amplifier is rated to provide less than 12.5
watts to an 8 ohm load, it will *not* be able to generate the
requisite 10 volts.

>Believe me I've subbed out 16 ohm speakers for 8 ohm, not only does
>the power drop but the distortion goes way up to the point that it
>would give you a headache.

Not true.

The power drops, but if the distortion goes way up it is *only*
because you have increased the volume in an attempt to get more
power than it can provide. If instead you had left the gain
control in exactly the same spot, and allowed it to deliver
exactly the same voltage (and a lower power), there would *not*
be any difference in distortion (that you could detect without
using some better than average test equipment).

Regardless, the trouble is that the output of the amp we are
actually dealing with is not going to be provided with a 8 Ohm
load. Or even a 20 Ohm load. It will have a 70,000 Ohm load.

And YIKES, it seems you missed the error I made in the previous
article, where I put the decimal in the wrong place and said
that would be 0.00014 watts.

Hmmmm...

```
E * E
P = -------
R
```

100
P = --------
70,000

or
1
P = -----
700

Or 0.0014 (not 0.00014 that I stated in the previous article, sorry!)

So... 10 volts across 70,000 Ohms will result in 0.0014 watts being delivered to the load. That is just more than a milliwatt, or 0 dBm, of power actually needed to accomplish the task.

Hence you do *not* need a 12.5 watt minimum output amplifier at all. What is needed is only something slightly more than 0 dBm, and that also means it must rated at that power into 70,000 ohms, or else the rate impedance must be transformed in some way to match the amplifier to the load. That is easy, and brings up the point that 8 ohm amplifiers probably are not the best possible solution, since a more obvious one is easily available.

Typically "amplifiers" with 600 ohm "line" outputs have a maximum output rating of 3 to 6 dB over the nominal 0 dBm output intended to be considered "normal". That means those amplifiers (virtually all stereo preamps, tuners, etc) are quite adequate for the use at hand, which needs 1.4 milliwatts.

The only trick necessary is choosing an appropriate matching transformer to boost the impedance from 600 to 70,000 so that the 1.4 milliwatt will be at 10 volts across the 70,000 Ohm load. The impedance ratio is 600/70,000, so a transformer giving approximately a 1:100 impedance ratio should be just fine, and most likely anything with a slightly lower ratio to a considerably higher ratio will also work very well.

It's important to protect the both the noise antenna input and the main antenna inputs on the noise canceller from RF - but trying to figure out if you should short or open the receiver input based on the wavelength is a little difficult when the frequency range covers a continuum of multiple octaves. Not to mention the problem with putting a quarter or half wave chunk of feedline between the changeover relay and the receiver input when the wavelength is 160 meters. That technique works well for any single frequency (or very narrow frequency band as a percentage of the center frequency) and is commonly used at VHF frequencies and above with diode and relay switching circuits for the additional isolation it affords.

An important consideration is the voltage on the changeover relay and the components connected to it. The obvious part is the 100 W and 50 Ohm situation, but consider what happens to the voltage when you have a high (SWR for the hams / VSWR for the engineers). Jason, since this is your project, I'll leave you with the research to figure out the potential range of reactive loads with various antennas as well as the calculation of the resultant voltages. Remember a good simulation models the real world, not just a convenient part of it. I will tell you the result if you don' t give this part of your design its due. Think about PCB traces vaporized, capacitors shorted, transistor "fuses", relay housings melted and what we used to call "essence of Allen Bradley" from the burned resistors. It's about the same as a lightning hit or running 1000 watts through a 100 watt unit! This can be a safety issue as well as causing unncessary delay and cost.

One of the other people noted that it was important to do a lot of reading, research and analysis of your own - I'll second that!

If you haven't run across it yet, start with the term "Null Steering".

'nuff said for now,

I knew they had to exist in the USA, because the same thing needs to be done wherever in the world you go.

So UK "cable gland" = US "liquid tight cable bushing"?

As a final check, do the people behind the counter in the electrical distributors speak the same language?

Please don't ask why they're called "glands" over here. I believe it's an old steam-age term for a part that looks rather similar... but it still doesn't say much for those old-time engineers' knowledge of anatomy.

The question seems daft, but bear with me, gentlemen. Has anyone ever
had an electric shock that they feel lucky to have survived?

800+ VDC off the plate supply of an old Gonset GSB-100 transmitter once. Fortunately, it was all along one arm. It knocked me across the room, and left a nice first-degree burn at the contact point.

Doubt I'd be around to type this if I'd been working with both hands at the time.

A couple, obviously not fatal, but enough to make me think twice about going for it again.

The first was as a young child, when I pushed a plug with no back on it into a socket using the palm of my hand, and the latest when I pulled a bare earth wire across a consumer unit prior to sleeving and terminating it, and it stroked the busbar. I took it as a wake-up call, and make sure that I have my rubber gloves on these days when doing this sort of work - or isolating the supply when practical.

I still get the occasional tingle (hazards of the job), but nothing lately like those other two, which _really_ hurt!

IIRC a "fatal" shock is mroe likely to be a mddling-current one. The stronger ones tend to self-defibbrilate you.

That's why lightning strike victims often survive.

A BAD shock I got once was when I had a pair of 400uf, 450V capacitors forming up on the cap tester.
It was up to 450 volts, but still pulling a few milliamps. I went to set it aside and wrapped one hand around one big aluminum can, other hand around the other can. I thought both cans were grounded, but somehow got a heck of a shock! Later on I realized I was chanrging the capacitors in series for some reason.

Take care,

George

Thanks, Leon. This is the kind of 'unsurvivable shock' I had in mind.
I'm sure we'll have several more hair-raising examples to come yet,
though.

Well, you can have shocks that would cause death if left untreated.
As some people get treated, they get to experience it all, apart from
actually getting planted.

I've seen someone get hold of 440 V 3 phase bus bars, one in each hand. He
was across the supply for about 5 minutes as the emergency stop button in
the lab didn't work and he couldn't let go. He was lucky - just badly burnt
hands. He was back at work a couple of days later, heavily bandaged.

Is is really? I talked to some guys who made defibrillators once; there was a defibrillator (a working one) in their lab, for use in case of shock while working on a defibrillator.

I got 600V/400MHz right through my little finger once. Reached in where I
shouldn't have. If the current had taken the long way to ground through my
feet or other arm, instead of the short way out the fingernail, I would have
at least been smoking from end to end.

My father had a 30kV (I think) shock (from a radar test set).
He went unconscious and many years later one could still see the scar
from the burn.

Once... 990 vac at 30 amps for a split second from right hand to left hand.
Stopped breathing, no heart beat but still aware for a few seconds.

How quiet everything got! Oh, I could still hear my coworkers laughing as I slid to the floor, but the normal, unnoticed noises of respiration and circulation were gone. About the time my vision started to go (seeing green, purple, black splotches, all else fading), my heart gave a great single beat then took off into tachycardia, then settled after a few seconds into a normal but fast rhythm. I could breath and see again, but was too weak to get up for several minutes. By this time the coworkers had figured out things were a bit more serious and I was helped to my feet. That's when I noticed the burn on one hand, where my thumb knuckle had brushed the case of the defective amplifier. It never really hurt, the burn spot, but my chest muscles were sore for a week, also took about that long for my strength return to normal.

I've been shocked many times before and since, but that was the closest I got to buying the tiny farm.

In 1948 I was working for Westinghouse motor and transformer repair. We had a LARGE transformer from a sub station to rewind. Always pot checked when repaired for insulation break down with 4000 volts. The hot lead had a pin hole in the insulation and the superintendent would not replace it. Had the worker wrap it with electrical tape. STUPID. The worker went ahead and used it. To reach the insulator tip the worker stood on a metal barrel covered with 2 by 4 wood. As the power was applied the 4K volts went through the hand, came out the foot and blew him off the barrel. He survived but had bad burns on hand and foot. No OSHA in those days. A week later I resigned from that job. Warren

1982 at Beal AFB while installing a 2.4MegKVA UPS system I received an
arc'd shock from a 992V DC Link that should have left nothing but a
pile of dust where I had been. For reasons unknown, it instead
through me 18ft against the opposite wall leaving nothing more than a
2 inch burn mark on my elbow, although it did take almost 4 hours for
my breathing to return to normal and I suffered extreme headaches for
3 days. It was also necessary to change both my underwear and pants.
To this day my left elbow is extremely and painfully sensitive.

960. Coils

I would like to build a coil on a 3/8th inch diameter tube about 1.5" to 2" long with an adjustable slug inside one with a rod of some type atached so I can turn it to adjust it.
They use to have such coils years ago made out of paper, however, now they are very hard to come by. I am wondering if such a form exists now or has something replace it. I am making a tank circuit for a small VFO and have all the parts except this one.
I am open to suggestions on how to build such a thing or where to buy one.
I asume plastic has replaced the paper tube.
Thanks so much in advance

Yes it is. 'Fatal' doesn't have any slack in its definition. You could modify it by adding 'near' as a prefix.

If the input impedance to the AF input on the signal generator is 70k Ohms then almost any little transistor voltage amp will drive it. I would expect maybe 1 to 2 volts RMS out if the sound card so it will be too low. Another simple alternative is to use an audio output transformer such as the Radio Shack 273-1380 and connect the 8 Ohm side to the left or right sound card output and the high impedance side to your signal generator AF input.

Use this information at your own risk, I'm not there to see just what you are working with. If you smoke your computer don't blame me.

963. fs: Kenwood kpt50 repeater radio programmer

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-08-07 17:16:28 UTC
From: Skipp has Kenwood stuff <skippNOSPAMPLEASE@pilot.ucdavis.edu>

Re: Kenwood kpt-50 repeater and radio programming unit

Hello there,

I've got one Kenwood kpt50 repeater / radio programmer unit for sale. The kpt50 works as a stand alone unit (has a keypad and a display) or with your pc and associated software via a standard rs-232 serial comm port.

This unit programs the Kenwood TK and TKR-720 / TKR-820 series repeater, base and mobile radios. It will also do (some of the) other similar Kenwood models.

This unit is probably my last one for sale. I sold them on Ebay earlier this year for various amounts up to $239 each. This is an original kenwood unit and yes I'm an Authorized Kenwood Two-Way Radio Dealer - Service Center and would be happy to supply any two-way radio - parts needs you might have. Drop me a note if you have any Kenwood Two-Way question.

This is a previously used unit, started life as my personal kpt50, lent it to "a friend" who had it over a year to program one "quick repeater job". Got it back just a short time ago. I will put a full new equipment warranty on it and provide copies of all the proper programming information. I had to use my last inventory unit in place of this unit while it went on vacation with my friend. Now it's back and I have one unit extra.

I used to program the tkr-820 (and 720) repeaters by hand using this type unit, but forget that... this unit has the normal rs-232 pc port access which allows you to do everything on your related laptop and save the data in regular archive files. Much nicer... I'll include a regular copy of the pc software with the unit, not bad.

Now the price, set below actual Dealer cost at $165 plus actual shipping, figure maybe $5 for USPS Priority Mail.

OK, that's about it. Drop me an Email if your are interested. If no one responds within a week or two, I'll toss it up on Ebay. Don't be confused by the "clone units" often listed on Ebay. Some of the associated programming units don't work on all the models. I know because I bought one myself before I became a Kenwood Dealer some years ago.

This is an original Kenwood made KPT-50 programmer.

That's about it, remove the NOSPAMPLEASE from my email address if you want to drop me a related message. My ebay ID is over 700 actual... all

positive feedback so I hopefully must be doing something right.

Thank you for reading this post.

cheers
skipp

skippNOSPAMPLEASE@pilot.ucdavis.edu

Remove the NOSPAMPLEASE else I'll never receive your message.

We call them cord grips at work. Pipe thread on one side, and a
compression gasket arrangement on the other. Available in metal or
plastic. Thomas&Betts and Hubbell are a couple of the brands we use.
They provide strain relief and a water tight seal to cords coming in
and out of electrical panels.

Randy,

Speaking of the horse's mouth! I am concerned that Jason might have too high an expectation of what the noise canceler can do. See if the below is right.

1. It can cancel out the noise from a single stationary noise source that is received via groundwave, and will in general do nothing for atmospheric noise as you would have on 75m.

2. For an automated adjustment method to work, and keep it within his means and time frame, he will have to tune to a frequency where there is no signal present. He should then be able to retune to a differenr frequency within a few KHz, and still have the nulling.

3. Consistent with 2, the receiver's AGC voltage is as good an indication of noise amplitude as any. In fact, it can't be measured AFTER the AGC, as for instance the audio output.

I remember hearing the story of an Air Force tech working on a 30' radar
dish. For some dumb reason, someone energized it and promptly microwaved
him to death.

Some of these stories are hair rasing... and I'm too much of a weenie to
stick my tongue on a 9V battery...

A Raytheon corporate legend is that one of the engineers discovered the
microwave oven principle when a radar melted a chocolate bar in his shirt
pocket.

A gland is a term for a liquid-tight seal on a moving/rotating shaft
in some industries here. Probably does go back to steam engines.

Some similar things might be called "explosion proof". This doesn't
mean it will be untouched in an explosion, but that flammable gases
won't get into the earea where sparks could happen in a switch or
other electrical device inside the enclosure.

Look to an industrial electrical supplier, not a residential-oriented
one.

>A friend once told me about how her son had tried to pry a fuse out of
>a fuse box with a knife and it threw him across the room

It's a myth that the electricity "throws us". Actually we throw
ourselves, because the electric current makes our muscles convulse. When
the big leg muscles really snap tight, they can easily throw you across
the room in a standing jump.

>and he couldn't move his legs for 20 minutes.

That's to be expected, considering what they just did! In heavier, less
fit people, it's not uncommon to rip muscles and tendons when a major
shock makes them try to do the impossible.

A former member of the Air Force told me about a safety training video narrated by a transmitter tech who did not observe *all* the procedures. He survived to make the video, but as a double amputee.

I was told that this training video was part of the curriculum for so many years that the principal character became somewhat of a celebrity. Perhaps someone with more direct knowledge can add or correct the details.

It even works for _on-channel_ jamming TX'ers off in another direction from the desired
signal (cable co's use
the technique). Separate directional antennas are used for the desired and the undesired
signals. The
undesired signal (jammer) is gain adjusted and phase shifted and then summed into the
"main" receiver signal
path at 180 degrees (and equal amplitude) from the same jammer entering into the main
antenna/rx'er path. The
obvious null for the undesired signal occurs. Nulling of the desired signal is highly
improbable given the
directional aspects of the antennas. The sum can occur in the rx'er front end. Yes, this is
signal
processing down at the microvolt level. One problem is tuning drift.

How much voltage is the 110V primary winding insulated for, typically? Is there a non-destructive way to find out? I've been thinking about achieving a 4x stepup by feeding 24V into a 6V winding and getting 440V. Even more, p-p.

Not as spectacular as the other stories here, my experience was with a Tascam data recorder - working on the front panel, (and, in retrospect, without due care and attention) I discovered that just because the circuitry is miniaturized and all the interconnects are ribbon cables does NOT guarantee some daft designer at Tascam hasn't decided to sneak AC mains in amongst the signal wiring.

Pray tell us how you arrived at this statement whioh I remind you is a matter of public record. Are you saying 2=10*10/20? 'cause that sure the heck looks like what you said in the following:

> On the other hand, if an amplifier rated to deliver only 2 watts
> into 20 Ohms is used... that too will deliver 10 volts, also at
> a miniscule power level into a 70K Ohm load, and work just fine.

But hey I haven't paid my, syntaz lately. You missed the error in your first post then you failed to correct it in your response. But yet you agreed that it takes 5 watts into a 20 ohm load to provide 10 volts. How touching.

Haven't read all the posts yet, but...Way back in high school ('bout 65-66), I was working on a TV set in electronics shop. I was in the back room, by myself, and had just turned it off. I was following all safety procedures, one hand to my side, other hand on the insulated screwdriver, prying off the 25Kv lead to the picture tube. Well we didn't know that the "decorative" metal railing of the work bench was grounded. My hand slipped off of the insulation onto the metal shaft off the screwdriver and I was leaning against the workbench. Next thing I remember was that I was flat on my back, with my head in the doorway, six feet from workbench. All the class were gathered around the teacher who said "My God! He's alive!" Turns out, they had heard the discharge (through me), and I had been out for at least 3-5 minutes. So I guess you could say I survived a "fatal" shock.

Years later, in the phone company, while reaching through some equipment to get a wire being passed to me, my forehead touch the +400V and my wrist touched a -400V of a telegraph (yes, telegraph) circuit. Didn't knock me out but it sure stung.....

Message-ID: <05CYa.40443$Ne.25582@fed1read03>
Source record: 33511

To all,
I am working with a DC motor that goes forward and reverse. The motor is controlled by a heat-sinked and fan cooled bank of 5 mj15003 transistors(5 each forward and reverse). On occasion the motors build up a high amount of copper on the armatures, from the brushes and this causes one of the 5 transistors to heat up and fail. The manual and the manufacture suggest matched transistors. What is a matched transistor????? I am guessing that they are tested and all have similar characteristics. But what characteristics am I looking for?? especially in a DC motor control.

Anyone have an answer for a semi technically literate person???? (i.e., I know the hot end of the soldering iron, from the cold end and have the scare to prove it!!!)

Thanks in advance....

A transceiver for this "band" was in the SEP 94 issue of 73.

I'd always wanted to put together a regen for this band. Regenerative
detectors are at their best when they are rather tightly coupled to
antennas that are electrically short. One reality of 1750 meters is
that any antenna one man can lift is bound to be "electrically short".

The above URL points to an app note ... however, I
didn't find a data sheet and it does not appear to be
in the selection guide or in an outdated parts section ...

It would appear that it may be a relatively new part
as opposed to an old one, though, because the app
note above is (c) 2003.

Reminds me back 20 years ago, I asked my young daughter to unplug an ice cream maker. I was watching her as she got a slightly surprised expression on her face and the GFCI did its job. Sure confirmed my belief in GFCIs!

Two shocks I can easily remember: 250VDC from the back of an NC-57 receiver, over 40 years ago, and I can still see the scar on my right index finger, and the CRT 2nd anode voltage from a color TV that made me sit down on the floor pretty hard. I suppose neither was very close to being fatal, just memorable. Interestingly, there's a nearly symmetrically-matching scar on the left index finger from different youthful folly.

Cheers,
Tom

http://www.rfparts.com/tranmatch.html

When an amplifier stage has two or more transistors, it is best to have all devices of the same gain and output to better equalize power sharing and d.c. current in each device. Other companies only offer matching of "Beta Codes" " hardly what matching is really about.

RF Parts Company has developed a testing program to provide the service technician with Premium Matched RF Power Transistors, having the best quality and performance. First, we select transistors with the same "Lot Number" and "d.c. Beta". (This is where others stop and call the transistors matched.) Next, we test each transistor's B-E, B-C, and C-E junctions with a curve tracer to separate out those with "undesirable" junction characteristics. Only transistors with low Collector-Base leakage (Icbo) are accepted for further testing. Finally, these "Premium" selected parts are placed in our RF Test Fixture, one at a time. The test measurement is noted on each part. Our transistor Power Gain test is measured at about 50-60% of maximum peak power rating. (Note: different drive power levels are used for the various transistors, and test numbers only apply for the particular part number under test.)

We select the best parts for matched sets of 2, 4, 8, 16, etc. The number on the outside of the envelope is the Power Measurement of each transistor as discussed above. Use of our selected parts will help assure top performance and reliability in multi-transistor power amplifiers.

Middlebrook's classic paper Measurement of Loop Gain in Feedback
Systems, International J. of Electronics, vol. 38, no. 1, pp. 485-512,
April 1975. IJE addresses this exactly.

If you do a Google search using Middlebrook Loop Gain you will find a
lot of discussion on how to do it in practice. One I found quickly
was http://www.venable.biz/tp-18.pdf which discusses measuring loop
gain/phase in a power supply via injecting a low level AC signal into
the feedback loop.

The statement is correct. When you read what I posted and
understand it, the statement then makes sense.

>But hey I haven't paid my, syntaz lately. You missed the error in your
>first post then you failed to correct it in your response. But yet you

It isn't an error. It is correct. As it says, an amplifier
rated to deliver only 2 watts into a 20 Ohm load can deliver 10
volts, at a miniscule power level, into a 70K Ohm load.

>agreed that it takes 5 watts into a 20 ohm load to provide 10 volts.
>How touching.

However, the above does *not* say that it will deliver 10 volts
with a 20 Ohm load. It says that it can deliver 10 volts with a
70K Ohm load.

In fact any amp that can deliver 0.0014 watts or more can
deliver 10 volts to a 70K Ohm load.

If you want me to explain it again, using different words, I
can. You probably will need an slight attitude adjustment to
really learn it though... ;-)

My first clear memory of my life is the few minutes immediately after of my dad's warning me not to poke a finger in a light socket while he fetched a new bulb. Dad left the room and 2-3 year old Eric headed straight for the (now empty) lamp socket. Amazing how clear a memory can be after decades.

The closest death by electrocution I've suffered was in the mid 1980's. Our disposal protocol required us to let air into CRTs. For some reason, I powered up the monitor before I disposed of it. I unplugged it, took the back off, donned my leather gloves, grabbed my uninsulated pliers and, with one hand on the steel case, snipped the nipple off of the 25" CRT. I remember the world getting almost completely covered by a big dark. I didn't get thrown or loose consciousness. My arm ached for a little while, that big dark is still with me from time to time.

Paul, are you asking if anyone has been killed, then revived? If anyone has made that journey, I'd be curious to know if your experience was similar to people who have survived a "fatal" drowning (great peace, white light, etc.).

My ham buddy and I built a 2 KW amp and 300w power supply. I think it was four 813s, and was used for the lower HF bands, 160 through 20m I think.

I used RG8 for the high voltage connection between the supply and the amplifier, and had purchased a proper high voltage socket and connector pair to interconnect it to the back of the amp.

One day when it was powered up, I reached behind to change the antenna, and it "bit" me good. The insulation on the RG8 had pulled back a bit, exposing the center high voltage conductor, and I brushed it with the back of my fingers. Not fatal, but it sure left an impression!

I still have the three small scars that are testament to my high power homebrew days.

An event like that can sure inspire one to run QRP!

Looking at the September 1983 issue of R&EW which contained the index for the first 24 issues:
Part 1 was in the Sept 1982 issue, pp 44-
Part 2 was in the Oct 1982 issue, pp 67-
An update appeared in March 1983
A further update was indicated for the October 1983 issue.

It would be as well to check later indexes to see if there were further updates.

There are people in the UK with sets of this magazine (Oct 1981 to ca. April 1989). Hopefully one of them can help.

Ray and Floyd,
Wow what an education. You both have given me the much sought after first steps to research. Thank you both very much for your explanations. The next step will be more research, by me, on both of your views.

Bob "who loves the input of others, but forms his own opinions!!!)

P.s. library here I come!!!!!!

p.s.s The little signal generator that could is humming along right now... audio out of the PC sound card, into a set of very old Sony powered computer speakers (which have a headphone output), thru a stereo plug, via cheap speaker cable, to the AF in of the EICO 324. AF modulation on the EICO is set for 100% (reading the manual, tells me that this is really only 50% rf modulation) RF antuation is set for none (rf coarse, set to hi) and rf fine is set to 100. The output from the pc speakers is set about 75% up... Sounds sweet coming from that big old 10" airline speaker in the next room. SO good in fact that my 9 y/o son, turned off the n64 just to sit in the dimly lit room and listen to the intersanctum!!!!!!...
Also note that I have trimmed back the antenna to a little under 9 meters, wound on a broomstick type antenna, and the band is set for the normal AM broadcast band. I also went around the yard and lost signal at the edges of the yard, except near the garbage cans,,, strange huh!!!...

I got one of those from a marine corps radar system (TPS-22).
We were supposed to use a metal grounding rod with wooden handle
and chain to discharge the high voltage caps. I held onto the
metal rod instead of the wooden handle. The thing was off at
the time, but the caps were probably at 10KV and it knocked
me across the room.

Tam,

Dave Schrader gave you the right short answers to your questions in a parallel post to this one; however, question number 2 is a bit constraining. Consider the fact that there are some substantial variations of the ANC-4 and MFJ noise cancellers that others have built as well as few that are floating around in my head and, I am certain, a lot of other peoples' heads. Nobody has mentioned these on this thread yet. Also think about the fact that armed with the same information and skill sets, engineers tend to simultaneously invent the same thing about the same time. Jason seems to have a pretty good tool box and a good understanding of how to add tools to it - witness this thead and his last project. So he may figure out a way to completely avoid a situation like the one you describe, maybe even costing less and being quicker to develop! If he cannot for some reason, then the challenge is to figure out a quick and easy way to do something like what you describe. The only problem is finding a different frequency a few kHz away with no signal present - especially on the ham bands! So maybe a little more reaching question is how does he find a better way to null a noise canceller? Of course, having said all that, sometimes the best engineering approach is brute force - do the obvious the way you already understand and get it shipped (or turned in to the instructor)!

Hmmm.... surely the noise will be phase shifted and altered in amplitude by a time-varying transfer function?You will need to estimate this first.

Sounds good to me!

All you need to boost the modulation percentage is the right
transformer. If your PC's sound card has a "line" output, that
will be 600 Ohms, and the discussion I gave about matching a 600
output would apply. Of course, the exact same effect can be had
from the speaker output, by using a transformer intended for
some low impedance to some very high impedance. The speaker
output probably can deliver more power, so the range of
transformers that will work is great, but the problem with it is
that there aren't many transformers around that will do 8 Ohms
to anything close to 70K Ohms.

Just try whatever you can find, because trying a wrong one won't
hurt a thing, and any step up in the voltage will increase the
modulation for you. (There's not much effect above about 70-80
percent though.) And, well... at 50% maybe you don't really
need to do *anything* more!

doh !!

I've had that article in a box for years (saved all my magazines), threw it out into the bin a few weeks ago in a big clear up.

Could have done you a scan ... sorry :(

>ADE-5s for awhile.

I just phone mini-circuts up directly and order straight off them (here in the UK). They have a minimum order value of ï¿½25 though - but it's easy to reach that figure with a couple of devices.

Have you tried contacting them direct ? ... give them a ring.

wrote:

>Paul, are you asking if anyone has been killed, then revived?

That's pretty close to what I'm getting at. What I *am* actually get
at is that theoretical physicists are coming around to the rather
extraordinary view that one cannot from one's own perspective be
killed by any sudden and dramatic life event. No matter how bad the
shock, you will always 'come around' to find that you've survived. The
tricky bit is that you'll probably have found yourself in a different
reality to the one you left. In the one you've left, observers will
see your cold, dead, smoking body lying sparko on the ground. Your
relatives will grieve, your obituary will be written. But *you* won't
know anything of that. You'll just believe you've had a lucky escape;
you'll go home and tell your friends and family all about it and years
later maybe you'll tell others via the Internet. Sounds nuts?
Incredible as it may seem, the majority of physicists currently
working in this field now believe this to be the case! And we're
talking world-class theoreticians here, not just the kooks who post to
alt.sci.theories.

IIRR the usual way of ending up dead from an electric shock is to have had your heart go into fibrillation.

The usual treatment for fibrillation is 4kV across the chest - the heart is a chaotic oscillator, and a decent shock disrupts whatever trajectory it is following at the time, and the new one has a good chance of being a regular heart-beat, rather than the ineffectual squirm of fibrillation.

When I was young and working on phased array diagnostic ultrasound, we got a short lecture on cine angiography, which gives nicer pictures of the blood flow in the coronary arteries, but at the that time the contrast medium that they had to inject into the heart to make the blood flow visible wasnï¿½t exactly heart friendly - you got to see about three heart beats at the normal rate, then a period of thrashing around.

Apparently, this period of thrashing around progressed to fibrillation in about 3% of cases, and they could restore normal rythm in about 97% of these cases, which suggests that quite a few people have had electric shocks that could have killed them - about thirty time more than those that died.

At around that time the EMI body-scanner crew were trying to do stroboscopic X-ray tomography on the beating heart, and utterly failed - even when beating "regularly" the heart is still a chaotic oscillator, and no two heart-beats are exactly the same. Our cardiologist was quite rude about the ignorance of the basics involved in starting down that path in the first place.

A guy I was working with one time told me he had one when working as an
electrician. He was working in the bottom of a 500V distribution cabinet,
laying on his back on the floor, when he Touched The Wrong Thing.

His parter, working in a cabinet a few yards away, heard a noice, looked
over & saw this guy's feet bouncing around. The partner bashed the
disconnect & pulled him out of the cabinet.

No heart beat.

Dead.

Good thing the other electrician knew CPR or this guy would still be dead.

He's in the IT field now, for some reason he felt the need for a career
change.

Source record: 33541

take a look at your power supply design cookbooks -- you will notice current balancing resistors on each of the transistors when they are paralleled.

if you purchase all of the transistors in one lot -- the MJ15003's come 100 to a package in a polyfoam container -- chances are they are going to line up pretty closely. if you are buying them randomly you can use a DMM with a transistor checker to measure beta. for current mirrors you measure beta and VBE, for MOSFETS you measure the VGS such that IDS = a specified current (100ma or 1 amp). International Rectifier has a section on their website on MOSFET measurement, but I haven't seen anything similar for BJT's from On-Semi or ST.

i spent a rainy afternoon "binning" transistors -- that is, I took a couple hundred MOSFETs and ran the VGS and Transconductance test, marked each unit (they were TO-247) and put the results in a spread sheet. From each "tube" of IRFP9240's the distributions were tight and normal. Transconductance was closely related (I also ran linear regression, r^2 was in the 90's) to Vgs(t).

i do have MJ15003's and MJ15004's from the same package, email me privately if you need them.

1025. Spectrum Analyser CRT drive problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-08-08 12:07:58 UTC
From: Hans Summers <Hans.Summers@Tudor.Com>
Message-ID: <bh03qu$t7vi6$1@ID-61331.news.uni-berlin.de>
Source record: 33543

Apologies in advance if this is considered OT.

I am having a minor problem with the display on my spectrum analyser Mk2 project, see http://www.hanssummers.com/electronics/equipment/spectrumanalyser2/index.htm . The display for this analyser is an 4.5-inch ex-TV tube. I successfully dismantled that TV and rebuilt the necessary drivers etc as a miniature monitor having TTL-level video and composite sync inputs.

Naturally the type of display this tube is now being subjected to is very different to a TV picture. There seem to be some problems with the video drive circuits, see pictures at the bottom of the above web page. The graticule fades out in the top eighth of the screen. Also see the "noise floor" photo which shows significant horizontal "bulge".

Also there is a resolution problem - one spectrum analyser sweep consists of 640 measurements, and I have a complicated interpolation circuit which "joins the dots" i.e. draws lines between the individual measurements, and also reduces the horizontal resolution to 320 pixels which I hoped would be displayable on the monitor. Problem is I can only get 160 horizontal pixels to display reliably - at 320 pixels a vertical line is very faint or invisible (depending on how much white there was in the preceeding microsecond or so's worth of scan line.

The circuit diagram is also on that page (http://www.hanssummers.com/electronics/equipment/spectrumanalyser2/circuitm .pdf). I'm no TV expert. Can anyone suggest what modifications should be made to the video driver circuit to correct these problems? Alternatively what newsgroup might be populated with TV gurus?

Would 1,500VDC with 6mA capability flowing through one arm and out the other be considered lethal? At one time, I knew how much current was considered lethal, but have forgotten.

My first job was at a company that manufactured electrostatic voltmeters, high voltage power supplies and high voltage amplifiers. I worked in the test department and calibrated just about all of the products. Among various test equipment, I used a +/- 1000VDC power supply with 1mA current limit. I swear, every time I was shocked by that power supply, the current limit LED turned on.

Randy,

Thanks for your response. The obvious thing you would like to do is to have the software be smart enough to distinguish between signal and noise. But then the hardware becomes moot, and you have invented a better DSP noise reduction circuit.

BTW, I am considering getting an ANC4 to get rid of power line noise on 6 meters. Fortunately, the noise is coming from the North, a very seldom used beam heading.

When I was in the army at Ft. Monmouth, NJ, we trained on a radar
trainer, had a klystron that put out 1W to the horn on the top of the
unit. We could put our finger over the horn and feel it get mildly
warm from the RF.

Big deal. The Real Thing put our 5 megawatts!

My ANC-4 is sitting on top of the ICOM 746. I have a short piece of coax, 7 to 8 feet, to a doublet with a total length of 8 feet on the floor against an outside wall.

Works Great!

I've used the ANC-4 for almost two years. While in Massachusetts the QTH was 100 meters from the New England Power Grid with three sets of high tension [> 67,000 volts] three phase power lines [nine wires total]. The power lines were generally quite quiet but during summer humidity and/or thunderstorms they would get 'noisy'. The ANC-4 reduced the noise to S1 typical levels.

Here in New Hampshire, my local noise source is the local LAN where the router is four feet from my receiver. Similar results with the ANC-4.

BTW, it was given to me as a gift by W1KSZ who picked it up on e-bay for about $60.00. Thanks many times over, Dick.

I agree. He said one thing, but meant another. Snot what you think!

Answer this question:

Q: Twenty years ago, a plane is flying at 20,000 feet over Germany. If
you will recall, Germany at the time was politically divided into West
Germany and East Germany. Anyway, during the flight, TWO of the
engines fail. The pilot, realizing that the last remaining engine is
also failing, decides on a crash landing. Unfortunately, the engine
fails before he has time and the plane crashes smack in the middle of
"no-man's-land" between East Germany and West Germany. Where would you
bury the survivors - East Germany or West Germany or in "no-man's-
land?"

DOH!

For the answer, and other similar Qs, see
http://dailyfunnies.org/archives/000637.html

I do. That particular style is also known as a "Winchester" connector, primarily from its use on early mainframe and minicomputer disk drive units (the big ones that look like small washing machines).

I've printed a picture of the unit to show my wholesaler. I don't think they'll have any problem finding a mate for it. I'll get back to you with a quote as soon as I have some numbers.

Yep, made me a believer in GFCIs, which weren't around when this happened.
My folks had just gotten a new hedge clipper, and their idiot son decided to
have at a shrub one morning. Plugged it in, walked out barefoot on the
still-damp grass. Began sculpting and promptly cut through the extension
cord, which jammed in the blades. My muscles locked up and I couldn't drop
it. After a few seconds of this I fell over, making even better contact
with the ground. I finally managed to grab the plastic side handle with my
other hand and pull it free. Whew.... Every part of my body hurt, I went
back to bed for the rest of the day.

Then there's the incident with the soldering iron and the ten automotive
batteries in series, but I didn't get a jolt from that ;-)

Regards,
Ralph in NH

Fatal is fatal. You're brain dead, which is the definition of death.
If you have a near-death experience, then that's when you can live to
tell about it.

"He's dead, Jim."

Actually, he shouldn't have been flying so close to the border. There was a
buffer zone between East & West Germany at the time and pilots were aware of
it. I think it was around 10 or 20 miles or so.

And I think burying survivors would be a violation of their rights.

Since it was 20 years ago, some of the survivors might be dead by now, so
the joke loses a little of its punch.

I've used such multiplier chips to go from 10 to 60 MHz, for example. Look
carefully at the jitter specs. You won't like them.

During his talk on the Software Defined Radio at the recent Central States
VHF Conference, Gerry Youngblood mentioned that they avoid programming the
9954 to certain frequencies in order to reduce the worst spurs.

Those operating frequencies are achieved by slight changes in the software
and setting the 9954 to a "good" nearby frequency.

No details were given and I didn't get around to asking for the details.
Does AD give hints?

One of the guys on a maintenance crew I was on in a previous job
and was doing testing with managed to get a nice 415vac 400Hz
across the chest.

Doing testing in mec relay panel the relays were in the back of the panel / box and
the doors are where all the circuit breakers are mounted.
remeber he made contact with the uncovered terminal of a transformer.

I was working with him as well as a few others, activating sensors(sticking a spanner in
front etc)
and he was confirming the right voltages were being recieved to activate relays etc.
Just heard a loud shout over the intercom and we all went running.

He was lucky he didn't get throw by it as he could have fallen about
10 foot on to the tarmac.

Just stunned at the time. Had to take him for a ecg afterwards
standard precaution. No problems at the time.

But his health seemed to deteriate after that.
Maybe it triggered an existing condition.
Six months later he suffered a heart attack.

From my own experiance, rf burns hurt more than
standard 50Hz ac or dc shocks even though I would have to
rate car iginition systems a close second.

I think I may have experienced rf burns some years ago. Is this when
you touch a metal object close to an rf field; it feels thermally
hot enough to burn you, but when the field is killed, said object
instantly feels normal room temperature again?

Does that mean that my smoking/exploding MOSFETs have narrowly
survived their "both sides of the half-bridge on" event in some
parallel universe? How about my dog who got runned over (sic) when I
was 12? Is he happily chasing various critters somewhere?

Best regards,

RF frequency burns are nastier than DC or low frequency, and are much
more disruptive to the body's electrical/nervous system.

They can also burn internally, with little outward burn shown.

A co-worker some years ago was sloppy, and put a few hundred watts of
RF through his hand. Nasty burn which took a very long time to heal.
Over 15 years, but I bet he still has a scar.

My advice is to avoid zapping anything you can't buy at the parts
store.

Happy trails,

Dave,

Thanks for the info. In my case, the source seems to be a bank of 4 transformers on a pole about 300 feet away. Weirdest thing I had was S9 white noise from about 40 to 55 MHz with about 50% amplitude modulation at around 50 KHz. Turned out to be a 60 amp cartridge fuse in my fuse box about to go bad. I think the 50 KHz was a mechanical resonance in the fuse.

I don't know about the 746, but my 756 has dual watch capability, which lets you listen to two frequencies at the same time. It would be interesting if they would let you vary the phase of the secondary channel..

There are lots of weird noise sources. As a kid in the 40s, I was part of a family visit to an old farm west of Bethlehem Pa., in what was definitely "fringe area" TV reception. The man of the house was telling my father about the strong zig-zag pattern that sometimes showed up on the screen, blanking out the video and often lousing up vertical synch. He wanted to know if the FCC would track down the interference; he thought it was a ham about half a mile away. Just then, the interference started, and right after, his son came downstairs to join us. A little while later, his daughter went upstairs, and the interference cleared when she got to the top. Without saying anything, I went over to the stairway switch and turned it on and off a few times. "On" caused the interference. When we swapped the bulb with one in a floor lamp, the floor lamp caused the same interference. It has been one of my enduring regrets that I didn't ask to keep the bulb. It was probably thrown out.

Any Home Depot or Lowes will have these, two to a bag under $ 2.00
At HD they are in the same aisle with the romex clamps and all emt/rigid
fittings.

m wrote...

We call them cord grips at work. Pipe thread on one side, and a
compression gasket arrangement on the other. Available in metal or
plastic. Thomas&Betts and Hubbell are a couple of the brands we use.
They provide strain relief and a water tight seal to cords coming in
and out of electrical panels.

here is a link for photo of a jbox you will never have to replace !

http://www.carlon.com/Brochures/2B10-6P_Rated_JunctionBoxes.pdf

Available at any home depot in electrical dept. under $ 20
depending on the size you need. You can drill it to accept
the weathertight strain relief that another poster recommended.

regards.

I'd check with the sci.electronics.repair denizens on this. They are
the undisputed video gurus of Usenet.

I imagine that it all comes down to bandwidth. Low video bandwidth will
translate directly into dim and/or smeary details. You may need to look
for some video-driver components that are expressly designed for
computer monitors (or oscilloscopes), rather than TV sets. Maybe it's
time to cannibalize an old IBM PC monochrome monitor?

I got 6000V from a Neon transformer once. Ouch! Only rated at 7ma, though.
The new one I got does 12000V at 15ma. I'm alot more careful now.

Well, that's a helluva way to become a celebrity! But on
observation, the amputee must've been a DOD civilian, because he
couldn't have remained in the AF without his legs. Or whatever was
amputated. Or maybe he did the narration after he had recovered and
was discharged.

1064. Motorola Advisor Pager

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-08-08 19:29:40 UTC
From: Colin Lowe <colinloweRE_MOVE_ME@jet.es>
Message-ID: <SWSYa.2368$w4.1432162@news-reader.eresmas.com>
Source record: 33481

Hi all,
I�m looking for tune-up info for a VHF Motorola Advisor Pocsag Pager.

I have booought a new Xtal and installed it and I can now send a message to the pager on 145.275 MHz using my Kantronics KPC9612 TNC. However the pager was originally on 153MHz and rather than just swop the Xtal I need to tweak up the receiver a little as I�m sure it will be deaf.

So if you have any tune-up info for a VHF Motorola Advisor I would like to hear from you.

I�m also looking for a Motorola Advisor or a NEC Provider with a highband receive board (171.325 MHz) for another project. If you have one keeping around the shack let me know how much you want for it.

Regards Colin

As for telco shocks...

Wasn't fatal, but sure was painful! Working in the Palm Desert, CA.
central office frame. The temperature is probably only 85-90, but still
had a healthy coating of sweat on my arm, and was reaching through the
frame when my arm rested on the wire wrap pins and someone hit it with
ring current! Zap, my arm jerks up, hits the wire wrap pins on the
block above, and someone hits IT with ringvoltage! Zap, my arm jerks
DOWN, hits the pins below just as another jolt of ring current...

Did this about three times! Arm was sore for a week, and my coworkers
didn't stop laughing for an hour!

How splendid! We call them Residual Current Circuit Breakers in
England. Typically they trip out at just over the amount of current
required to kill someone. Keeps the bills down that way. In *this*
universe, anyway.

Ground Fault Circuit Interruptor.

It detects a sudden rise in current to ground and shuts the circuit
off in a fraction of a second.

Fuses protect the circuit, GFCI protects people.

The present US Electrical Code requires them in areas where water is
nearby, including bathrooms, kitchens, garages, and outdoors.

You are encouraged to use them in other places where there is danger
of zapping yourself.

They are not a guarantee, but they boost the odds in your favor.

Happy trails,

I'm interested in experimenting with phased arrays, but I can't find
any variable delay lines. I don't want coils of transmission line --
what I'd like is a little widget that can be tweaked to change the
amount of delay, but I don't see any of that for analog stuff like
transmission lines, just digital stuff like TTL logic. Help?

Jack.

We meet in the oddest places, Jack, and this one's as odd as any. ;=)

For receiving, you could use voltage-biased varicaps; I know that lots
of VCRs use delay lines in which the variable elements are varicaps,
and the first such I encountered was an Ampex FR-900, back in 1966.
Linearity could be a problem, of course, so you might have to have
a DAC doing the biasing based on table lookup of the desired delay.

For transmitting, I think even the military use lots of coils of
transmission line, though I'm not privy to the innards of the
modern stuff. Scientific American had an article on phased-array
rigs in Feb. 1985; your library probably has a copy.

Sure, but the pulse width is only a microsecond, so the
average power is only 5 watts at one pulse per second.
I forget the rep rate of the one I woked on but at
6uS per mile and 400 miles round trip, the rep rate
would be about 400 Hz. So it's 400 times 5, or 2KW.

The only way I've used variable capacitors (which is what I'm thinking
varicaps expands to) is in antenna tuners. A quick Google doesn't
show any circuits for using varicaps in delay lines, but television
stations apparently used them way back then.

I was considering ADC-digital delay-DAC but I wasn't sure how much
signal quality would be lost in translation. I also must confess I
wasn't exactly sure what sort of voltage/current/etc would be expected
over the transmission line.

During my junior lab while working for a physics degree, we had to build a gas flow geiger counter to count cosmic rays (the cosmic ray group ran the class). The 5000 volt supply we built for the tubes had no current limiting, so the current limits of the components was all the protection we had. I got 5000 volts to the tip of one of my fingers while working on it, it left a nice brown spot that lasted for several weeks. That wasn't the scariest shock event in my life, I was driving down the highway, and felt the hair raise up on my arms. Then there was a boom and my car radio stopped working. That was the one time that I was in a lightning event. Fortunately that was years before I was a ham or I would have lost several more radios at the same time.
thanks, John.

I wouldn't count on it.

My Brother-in-Law lost a leg while in the airforce and served more than
20 years after that before he retired, picked up quite a few promotions
along the way.

I think you will find that amputees have served in the USAF, RAF, RCAF,
RCN and probably several other military services over the years.
Admittedly they lost their limbs after they joined the service.

From what I can recall one USAF aircrew member lost a limb in a (B-47)?
crash, the RCN guy lost one after his aircraft went off a carrier and he
passed under the carrier and lost, I think a leg. The most famous is
probably Douglas Bader who lost both legs and went on to serve as a
fighter pilot in WWII. One thing they all have in common is that they
fought like hell to stay in.

Dave

The example above sounds more like inductive heating.

If an ungrounded piece of metal is near an RF energized coil, a
current is induced in it which heats it up. Somewhat similar to a
microwave oven.

> to write it." - Winston Churchill

Nothing like that, yet.

Rewired some factory emergency lights and replaced several more, one leg of a 480V circuit, live. Work careful and no problems.

Removing a high-pressure bulb from a high-voltage circuit, glass envelope broke in my hand while trying to unscrew it, didn't know I could move that fast.

Rewiring a conveyor, co-worker said the power was off, sparks flew when I cut the cable. I just stared at the remains of my pliers and then at him. ONE HAND in contact with the work, nothing else, work on insulated surface, heavy rubber sole boots, and anything else I can think of.

Worked at one plant that had had a color blind electrician, that really taught me caution, never knew what color wired carried what voltage.

Hey Charles,

When I was a "frameman" (oops, make that "frame attendant") in the Alameda Central Office, had exactly the same type of "shock". Air conditioning had broken, we were in t-shirts, about 90+ degrees in the CO on a summers day and sweating. Reaching through the frame from the equipment side hit someone who was ringing and became a human bell clapper for about 20-30 seconds. All this at the top of a rolling ladder. My fellow employees and myself got a laugh out of it (me later). Actually happened a few times over my 27 year career. At least I'm not unique in that sense. Thanks for sharing......

1087. Re: Question about delay lines

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-08-09 04:27:13 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vj8u162nuprddb@corp.supernews.com>
Source record: 33404

The only variable delay lines I've ever seen with the delay variable more than a couple of nanoseconds are some units used in an old Tektronix instrument of some sort. They're awfully rare.

Of course, even transmission line delay lines produce a delay equal to the electrical length of the line, and a voltage or current transformation ration of one, only if terminated in their characteristic impedance, or a few special cases. And the impedances of elements of efficient arrays vary all over the map as phasing is changed. But a variable delay line (most often implemented as binary-weighted lengths of transmission line that can be switched in and out) can be practical if the array elements are electrically very short and/or lossy, to swamp the effects of mutual Z(*). That means it's practical for a receive array but not so practical for transmitting(**). You'll find more about this in Chapter 8 of the ARRL Antenna Book.

You might be able to make use of some of the tapped digital delay lines (for receive only or very low power levels, of course) if you can compensate for the insertion loss and frequency-dependent characteristics. Another option is L networks. Although these can be adjusted for various delays, it would be tricky to make an adjustment arrangement that would adjust the delay without also changing the voltage and current transformation ratio and the equivalent characteristic impedance -- both elements would have to be adjusted together in a particular way. Of course, you could make a series of L networks with binary weighted delays and switch them as you would transmission lines. The disadvantage is that the L network delay and equivalent Z0 will change with frequency, while those of real transmission lines won't.

(*) It's also practical if there's a very large number of elements, so that each element is effectively in the same environment as all the others. I worked on a radar using this principle back in the '60s. It had switched delay lines to steer a transmit array of 10,000 separate transmitters, each with its own antenna, and a receive array of over 5,000 separate receivers, each with its own antenna. It was actually the phasing of the Tx and Rx local oscillators which were controlled, though. Last I heard, it was still in operation.

(**) If you build a receive array where the signals are combined in a low-loss fashion, you encounter exactly the same problems as for a transmit array. Lossy summing networks can stabilize the impedances and simplify the job just like lossy elements can.

I worked college summers as an electrician. Cut a live lamp circuit with my brand new pliers, leaving a 14-ga notch.

Years later, I saw "my" pliers in the lab tech's toolbox. He said he had done the same thing a few years back. I didn't really believe they were his until I found my old pliers in the bottom of my garage toolkit.

Eric,
In my days as a Frame Ape, I got across one of the Darned Gov't special
circuits that had a lot more than ring voltage on it. Only once though,
I can still remember the special warning tags they hadon the lines at
all the blocks, and like you Iwas at the top of the ladder when it
happened. And oh yes I also got bit by ring more than once. Remember the
way we found shorts?

That may not be an accurate translation. As I understand it, the GFCI requires a ground connection in order to operate, while the RCB does not.

The RCB functions on the difference between the outgoing 'live' current and the return current in the neutral. In the British house wiring system, those two currents should be *exactly* equal, and the difference (the 'residual current') should be zero. Any difference at all means something's wrong - ping - you're disconnected.

A typical household RCB will trip on a 60 or 100mA difference in supply current surges up to 60A. That's pretty good common-mode rejection!

RCDs can also be cascaded, so an even more sensitive RCD can be used to protect an outdoor mains socket or a workbench.

We used to have something like GFCIs over here, but changed to RCDs because RCDs still work if the entire house ground connection has failed.

I don't see how it can be. The metal in this case was only hot whilst
the RF was flying about. It was cold to the touch the second the power
was cut. If it takes no time to cool down I infer there's something
more to it.

No, the GFCI doesn't need the safety ground. Like the device you're describing, it measures the difference between the "hot" and "neutral" wires, by running the pair together through a transformer. A GFCI is supposed to trip in 1/40 of a second at 5 mA.

In our system, like yours, the "hot" and "neutral" wires should always carry equal currents, and the safety ground shouldn't carry any. However, the safety ground is sized the same as the current-carrying conductors so it'll handle a fault current large enough to kick the circuit breaker. Its primary function is to protect against something like the "hot" wire making contact with a metal appliance frame, which should be connected to the safety ground. When it comes to a GFCI, no assumption is made about how much of the imbalance current is returned via the safety ground and how much via the Earth or some other path.

That bulb was probably an old coiled 'Edison' type . They were /are known to
form a tuned circuit resonating in the old TV band 1 (about 48 - 62 MHz)
acting as a TX when power is applied.

Don't want to be pedantic but the RCDs in domestic switchboards in the UK
(at least here in Scotland) trip at 30 mA .
I just had a look at my house's switch board made by SQUARE -D (England)
to British Standard BS5486 pt 13

In UK industry I have come across RCDs which trip at 100 mA

Sorry, I got mixed-up about that. Our house was wired under the older regulations which allowed the lights to be protected by a separate 100mA RCD, while the power outlets are protected at 30mA. The idea was that tripping a power circuit is less likely to plunge the whole house into darkness.

The standard for new household installations is now 30mA all around, although 100mA units are still available for industrial uses.

That is pretty much the same as our RCDs, right down to the large-sized 'protective earth' wire.

>Its primary function is to protect against something like the "hot"
>wire making contact with a metal appliance frame, which should be
>connected to the safety ground.

An interesting thing happens when you switch off to isolate part of the house wiring, and then cut the "dead" three-wire cable. (We call it "flat twin and earth". It has PVC-insulated hot and neutral wires with a bare ground wire in between, all in a flattish grey or white PVC sheath. Is this what you call "Romex"?) If you cut the hot and ground wires together, nothing happens; but if you cut the neutral and ground wires together, the RCD trips. That's a puzzle the first time it happens, but it's because that cable isn't quite as "dead" as you think. the isolating switches interrupt only the hot wire, so the neutral and earth are still being shared with everything else that's switched on in the house.

Does that happen in the USA, or do you have two-pole isolating switches for individual sub-circuits?

This isn't totally idle curiosity. If there's an electrical problem while we're staying with the in-laws in Atlanta, I'm the one who's supposed to know about these things...

>When it comes to a GFCI, no assumption is made about how much of the
>imbalance current is returned via the safety ground and how much via

>
Exactly the same as our RCD, then... just a slightly ambiguous name.

Radio Shack used to sell a voice chip in a kit that let you record and play back either 10-15 seconds of audio, or another one that I think could have 4 messages up to 5 seconds each. All you had to do was add a battery. Many modified this into an
enclosure with relay for PTT for a one-button voice keyer. I think the chip is still available, but not from Radio Shack.
Try some of the electronic supply houses.
You could probably easily then make the
interface from the pc to the voice kit.

Alternatively, there are a number of logging programs that have the capability for voice keyers right in the software. I think Logger and N1MM are 2 of them, and N1MM is free. N1MM is a contesting software being developed by N1MM, but a also a group effort. Keying is CW, voice, Data modes.
Visit n1mm.com.

Good luck.
Bennett ko2ok.

> Worked at one plant that had had a color blind electrician, that really
> taught me caution, never knew what color wired carried what voltage.

I knew a color-blind guy who sometimes worked on the electrical
wiring, and his technique was to very quickly touch the wires together
to see if things worked. Problem was, often this resulted in sparks
big time!

This guy got hired on as a grape picker when he was young, and others
were wondering how he filled up his basket so quickly. Turned out he
was was picking a lot more than just the ripe ones!

See, color-blind guys (most of the time, women are seldom color-blind)
have never been able to see colors, so they don't know any difference.
And they often think they can do what they really can't. If you'd
been told by others that this color that looks the same to you is both
red, orange and green, you'd just say that they didn't know what

they're talking about and do whatever you thought was right.

And since wire color codes are so important, the color-blind
electrician or technician is a real danger to himself and others.

For a really cool color perception test, see URL
http://www.toledo-bend.com/colorblind/Ishihara.html

I used to be able to do that with the nickle plated antistatic bags
that parts came in back in 1980. The ohmmeter would measure several
hundred ohms. But nowadays all I can measure is an open. I just
tried it again, measured open even on the 200M range.

Has anyone come across K01252-d co-ax cable and/or could tell me what its basic spec is ? I think its made by Huber + Suhner but I don't seem to be able to get into their web site at the moment to check, I need a length of thin co-ax to finish a job off & all I can dig out of my junk box is a reel of this stuff. Looks good quality but (like me) years old !!!!

Think of "30-30" as a mnemonic.

If the source has over 30 Volts and can supply over 30 milliamperes
through the cardiac region, you will go into cardiac fibrilation.

High voltage with little supply current will affect the nerves and the
resulting muscle spasms can cause other kinds of injuries, some
that may be fatal.

DON'T DO IT. PAY ATTENTION!

That's been an Urban Legend for decades...probably a PR plant from
someone at Raytheon's Santa Barbara, CA, division that deveeloped
the RadaRange (originally a trademark of Raytheon before they sold that
consumer line to Amana).

========

While all the war stories and chit-chat are entertaining, please consider
a real-life tragedy that happened to a TV broadcast van in Los Angeles
last year. The van had stopped and erected its field-to-transmitter link
dish to Mount Wilson where the TV transmitter was. Standard
procedure here to get a clear shot above buildings and obstructions,
all the field vans have such erectable dishes.

Nobody in the field crew seems to have noticed that the van was under
a "high-line" of higher-voltage lines common in local area power
distribution. The dish and its two-section small crane came in contact
with the high-line. Somehow the kind of contact sent a good-sized
electrical power flow down into the van. A woman reporter was severely
burned in addition to being knocked unconscious...burns severe enough
to require amputation of part of an arm and part of a leg. She survived
but spent many months in the hospital and physical therapy, had to use

a wheelchair to get around even though active and healthy and not yet 40 before the accident.

This incident was clearly a result of STUPID NON-ATTENTION by the TV field crew. That high-line distribution is common all over this city and adjoining cities. To erect the link dish right into power wiring of any kind was just compounding the stupidity.

I mention this because amateur radio nearly always involves outside antennas in urban areas close to utility power wiring on poles. The possibility of fatal or terrible electric shock isn't confined to some radio-electronic box interior...it exists out in the open, in plain sight. Keep it in mind to avoid frying that mind.

Len Anderson
retired (and still living) electronic engineer person

=====
That family of integrated circuits is made by Information Storage Devices
Inc (ISD) ,San Jose -California
The early types (1992) were ISD1012A , ISD1016A , ISD1020A with
Record/Playback duration of 12 , 16 and 20 seconds respectively . The
respective upper pass band limits are 4.5 , 3.4 and 2.7 kHz.
They have an onboard mic amplifier , automatic gain control ,antialiasing
and smoothing filters and a speaker amplifier.

A number of units can be cascaded to increase overall Record/Playback
duration.

> Tektronix instrument of some sort. They're awfully rare.

Oh, they exist. They're often used in simulcast radio systems at
each transmitter site. The idea, of course, is to insert a calculated
delay into the modulation so that the audio signals from each site don't
end up phase-cancelling one another.

Allen Avionics is a big maker of variable delay lines. You may
want to check Ebay for them.

Sorry, Len, but I can't see it. I routinely check for HV on the anodes
of certain smallish valves with bare fingers and can't even begin to
feel anything under about 80 volts (at very much more current
capability than 30mA) at the low end. However, I read somewhere that
some guy died from just a 12V 'shock' - must have been a world
record.. :-(

Yes, that's "Romex". The official designation is type NM (for Non-Metallic). 12 gauge wire, for 20 amps maximum, is "12-2 with ground" and 14 gauge, for 15 amps, is "14-2 with ground". Those are the most common sizes for residential lighting and outlet circuits.

I don't quite follow where you're cutting the wires or where the RCD is located. Here, you can get a GFCI as either a circuit breaker you install in the service box to protect a whole circuit, or incorporated in a duplex outlet. Both are easily identifiable by the conspicuous test button. The breaker differs from an ordinary breaker in that the neutral wire is also routed through it.

Circuit breakers interrupt only the "hot" wire. It's been a long time since I studied the code (NEC - National Electrical Code), but I'm sure that switching the neutral is still a no-no. Neutral wires are all brought back to the service box, where they're all connected to the central power feed wire. The safety grounds are brought back to the service box separately, where they're connected to the same point as the neutrals. Neutral and safety ground are connected together only at the service box, nowhere else.

I'd at least get a home-handyman book on electrical wiring, and a real code book if you'll be doing anything other than pretty simple wiring. The rules are quite complex, dictating things like how close to a junction box wires have to be supported, how they can be routed, what size junction box is required for various combinations of entering/exiting wires, etc. In Oregon, wiring can legally be done only by the homeowner or a licensed electrician, but each state and many localities have their own rules. I think all, or just about all, the states now at least have agreed to use the NEC. (You're probably technically forbidden to touch the wiring, depending on Georgia and Atlanta regulations.) The presence of non-code wiring could result in non-payment of insurance if a home were to have an electrical fire.

I wired the addition to our home, which involved adding seven circuits including outside outlets and lights. I also replaced and upgraded the service box. Those jobs were done with electrical work permits, and both were inspected and passed. So I have done a bit of this before. But it was a lot of years ago now, the code evolves, and my memory fades.

About a year later, I read about such a bulb in QST. The author believed
that Edison-effect electrons excited a self broad-band resonance in the
doubly coiled filament, sustaining oscillation by a mechanism I forget,
but that seemed reasonable at the time. Incandescent lamps are filled
with low-pressure nitrogen to avoid damage from the Edison effect, and
interaction with the gas figured in his explanation. It was that
explanation that led me to build an open-air triode. I was surprised as
anyone when that worked, and I took it as a confirming instance for the
now-forgotten explanation.

Thank you thankyouthankyou! I've been called a crazy liar more than once
over that bulb. There was no channel 1 when that incident happened, but
I suppose that a small change of geometry could raise the frequency. The
explanation in QST had it that the frequency was swept over a fairly
large range as the voltage varied during a cycle.

I dunno, Tom, that's probably pushing things. You could re-insulate the low voltage winding by taking the tranformer apart, using some thin HV insulating material, tape, whatever you're sure would handle the HV youi plan, and then rewind the secondary back on. This assumes the secondary is wound on the outer layer, which is usually the case. Make sure to rewind the same number of turns, and be careful to not overfill the space with insulation such that it all won't fit back together.

Well that is funky!

Got electrocuted pretty well as a teenager. Fiddling about with an
ex-Army ZC1 set I'd converted to mains, managed to take 230vac from
arm to arm for what seemed like several minutes, but was probably a
second. Was sick, shaking, sore and sweaty for a couple of hours,
still had sore muscles for several days. Not at all funny. But the
universe I came back to seemed pretty normal.

Did the NDE thing after drowning in the school pool as a kid though,
can pretty clearly recall looking down on myself, and the teacher
"bringing me back" I suspect she still wanted to hassle me about the
unfinished homework, and drowning was not going to be accepted as an
excuse! Still the same universe though!

Well, years ago I got nailed by a 15 kv neon transformer, and I found myself on the ground seeing electric cartoons, Chinese algebra and vibrating light bars. After struggling to make the chest muscles relax enough to inhale, I decided that there were safer things to mess around with- yeah, for about a week!
But the only NDE I have had was the end of June of this year, after a vicious bout of food poisoning after eating at Golden Corral here in Orlando. I was so dehydrated I could not sweat, with a temperature of 104 F (that's 40 C for all the metric people). I spent most of the time that I felt hot in the shower, soaking. On the third day, early in the morning, I had the bright light/dark tunnel experience. Even now, when I start to think about it, it is difficult not to tear up. It was a most interesting adventure and one that really hit deeply in the emotional center.
I can see why so many people feel so moved or changed by it, but I was pretty much "there" already, so it has only left a few marks on me.

Cheers!

>made to the video driver circuit to correct these problems? Alternatively
>what newsgroup might be populated with TV gurus?

If there is a "fade" of part of the screen when doing off-on switching
of the CRT (either grid or cathode, doesn't make much difference),
the fade can be due to simple AC coupling between the off-on
driver circuit and CRT circuit. The CRT needs a DC coupling to keep
the baseline constant. AC coupling will "move" the baseline
depending on the capacitor-load-resistance time constant.

If the top of the display has faded towards black, then one can guess
two things: The CRT cathode is being driven negative to turn on the
beam and there is AC coupling to shift the baseline and thus the
"on" pulse tips towards black level.

"Fuzz" or "smear" on the display for fine detail is invariably a band-
width thing. Poor high frequency response in the video driver to CRT
will cause that. That can be overcome by "peaking" techniques on
the driver circuits, first done six decades ago or so with tubes/valves.

Very nice construction on the little TV conversion to display on your
website! :-)

>
>-Bill

A very rough estimate of "radar range" (time out to return of echo) is 500 feet per microsecond. For a 200 mile search radar the time out to echo return is 2+ milliseconds, depending on whether it is calibrated for statute or nautical miles. Typical PRF for those 200 mile search radars was 400 Hz (PRT of about 2.5 mSec).

Average power output is Peak x ((pulse width)/(repetition time)) or 5 MW divided by 2500 = 2 KW.

2 KW concentrated in a 2 to 5 degree cone can have a devastating heating effect on human tissue.

One may or may not be "in" the cone of the beam right up close to the feedhorn but, with the construction of most search radars (maritime or ground) there isn't much walk-around space to get away from the feedhorn or the very close in-person effects of microwave radiation.

When working on HIGH POWER RF at any frequency, believe in the inverse square law and put as much distance from the antenna as possible...or have a trusted person down on the power controls who keeps the thing OFF while up there doing whatever.

I think it would be an interesting subject to compare peak power RF effects versus average power RF effects. I can't seem to find much on that in hundreds of pages of medical-biological reports on the effects of RF radiation on human tissue. Unfortunately, that has been pretty well shunted aside so that someone can get their pet "alternate universe" speculations going on in here. :-)

All this gee-whizzy speculation stuff leaves me shocked.
But not fatally so...

Only 120vac on a 20 a bench lab supply,
in radio shop back in 1975 building radio from kits, tubes.

One of the pot heads could not get his radio to work,
so he asked for help and like a stupid jerk I say ok.

I wanted to look it over first before I plug it in,
so I have it in both hands, then pot head plugs in the radio,
next thing I feel is my hands getting tight grip on the metal
cabinet, my chest and heart start to feel the electricity and
I slowly feel that I am starting to black out.

Luck for me the power cord was still coiled up from factory,
I was able to lean backwards and fall off the lab
chair and that caused the plug to pull out of the outlet.

I hit the floor hard but did not feel it due to my body all
numb from the shock.

>record.. :-(

I'm not concerned with what YOU do personally, nor will I set any
"standards" for all humans based on what one human can or can't
do or feel.

I got the "30-30" phrase while working at Birtcher Instruments, a
semiconductor test instrument maker and a division of Birtcher
Medical that made several different medical electronic instruments
(EKG, RF knife/cautery, defibrilators,etc.). Someone at Birtcher
Medical told me about it. I was Chief Engineer at Birtcher Instruments
in Monterey Park, California, a suburb of Los Angeles (not the upstate
Monterey, CA, where some FedEx deliveries went, hi). I don't think
that my employer at the time would give me false information.

The City of Los Angeles building and safety codes don't require
inspection of 24 VAC wiring in residences and that sort of wiring is
common here for furnace and HVAC controls, doorbells, etc. That
AC voltage is never considered "high voltage." That is probably true
of the USA National Electrical Code although I haven't read one
recently (I've only read the coding in the Numeric Electromagnetic
Code recently, quite different from the other "NEC").

I really don't know the medical-biological low threashold for direct
cardiac stimulation through an opening in the chest cavity. I don't
care to know. I care to know NOT to futz around with my or anyone
else's body with anything above the "30-30" limits.

If YOU want to experiment with your own body, feel free. Then you
transport yourself to that other "reality." When you get there, ask
someone there to shock themselves into this reality and tell us all what
it is like "over there." I live in THIS reality where survival depends on

not treating electricity cavalierly like it was words in a newsgroup.

Happy zapping.

>a 4x stepup by feeding 24V into a 6V winding and getting 440V. Even more,
>p-p.

The insulation MIGHT be figured as twice the maximum peak-to-peak
AC swing to all other windings and their twice peak-to-peak values and
the core and frame. No guarantee, just a rule of thumb.

A "non-destructive way to find out?" Absolutely. Get an old plate
transformer of about 250 VDC kind or higher, put a variable auto-
transformer on the input, and series the secondary through a very
high value resistor, say around a MegOhm, to the device under test.
Use a scope to measure the AC across the device under test.

Bring up the autotransformer (trade names Variac - General Radio -
or Powerstat - Superior Electric) voltage from zero and watch the
scope waveform. When it starts to break up, that's the breakdown
voltage, approximately related to the variable autotransformer setting
and the ratio of voltage step-up of the test transformer. The series
resistance value limits the short-circuit current flow; with 1 MegOhm
and, say, 400 VAC, the maximum current flow would be 0.4 mA AC.

Any "HiPot" tester (former Brewster Electronics) can do the same
thing.

The design and capabilities of transformers are covered in essence
in the old "Green Bible," or ITT Radio Handbook for Engineers, circa
1950s. Also the "Blue Bible" of the 1970s and later. There's a lot
more to power transformer design than realized. You CAN get a
voltage step-up as you described but you will NOT get the rated
currents into any finite load. I will let the "student" figure that one
out.

A coarse approximation of winding a small power transformer is to
figure the number of turns per volt per winding as the E-I core center
square area in square inches divided by 6.5. Choose wire size to
handle the current. That's only for estimation purposes since there are
lots of variables involved. I'm not saying to rewind anything, just that
you will probably get the increased NO-LOAD voltage, but that will
drop depending on the equivalent load resistance.

>the service box, nowhere else.
>

On our single-phase 230V systems, we have two different ways of connecting neutral and ground. The old way is to have a separate individual earth rod at each house, with no connection to neutral in the house wiring. However, the power company's neutral is cross-linked to earth (maybe in several places) so neutral is always pretty close to earth potential.

The more modern way, called "Protective Multiple Earthing" or PME, links the protective ground to neutral at each house, directly upstream of the RCD, but the house has no physical earth connection of its own. The power company provides multiple earthing connections in its network, so there's always one not far away, and once again neutral is pretty close to earth potential. PME is supposed to be more reliable than individual earth rods at each house, but the Wiring Regs do not like people to add their own earth connections... which makes real problems for radio hams supplied by PME systems.

Coming back to the RCD question, it seems that our breakers/isolators for individual sub-circuits in the house (eg "upstairs lights") interrupt the live/hot line only. When you "isolate" the sub-circuit you're working on, the hot line is dead and safe... but the neutral and ground mesh for the whole house is still connected.

Now when you snip through the Romex, if your cutter blade connects the neutral and ground wires, it creates a sneak path between neutral and ground for all the other sub-circuits in the house are that are still active, and that pops the GFCI/RCD. It's a surprise the first time it happens - especially if you've rigged a temporary worklight from another sub-circuit, and especially if you find yourself kneeling on the rafters above the bedroom ceiling, suddenly in total darkness! Such experiences tend to concentrate the mind, so then you learn to nibble through the cable more carefully, one wire at a time.

>> This isn't totally idle curiosity. If there's an electrical problem
>>while we're staying with the in-laws in Atlanta, I'm the one who's
>>supposed to know about these things...
>
>I'd at least get a home-handyman book on electrical wiring, and a real
>code book if you'll be doing anything other than pretty simple wiring.

[Snipped some very good advice]

I'd never be involved in new wiring; but in our transatlantic family, I'm expected at least to understand what I'm looking at.

Actually the in-laws' house was built quite recently, so the wiring seems to make sense. Our wives' parents' old home in upstate NY was quite another matter... to British eyes, the wiring in there was downright scary.

It's pretty clear that US and UK household wiring practices are now converging on the same basic principles, subject of course to the differences in your "split-rail" system and ours.

Then there are the additional eccentricities that things like wiring codes will always have. There are often many safe ways to do it, but the only acceptable way is The Code's Way.

> But it was a lot of years ago now, the code evolves, and my memory
>fades.

That's a real problem - the code evolving, I mean... not... what was the other thing?

==========
To overcome ANY bulb problem I would suggest you check the supply voltage to the bulb.

If DC replace the bulb by a LED and a suitable series resistor . If AC add a diode (with suitable PIV) in series with the LED and the series resistor. (Although the LED is a diode , it has a low PIV ,hence the requirement for the additional diode).

As a general safety rule I'm sure you're right. However it does
overlook the fact that different individuals have different tolerance
levels, hence the fatality at 12V (the only recorded one, I believe)
and that Polish electrician who checks for the presence of 230VAC by
sticking his fingers in light sockets where he perceives a "slight
tingle." I personally can't feel 60V dc *at all* and would be
interested to know of others experiences of the lowest voltage they
can feel - without suggesting anyone do so, of course. Based on past
experience, I suppose.

When I am around high voltages, I practice the "two-hand rule" - I keep both hands in my pockets and don't touch anything.

Yes.

Their is a chip that's now being used on the newer intel P4 mother boards (to report boot up problems etc).

The same chip is also used here ...

<http://www.robot-electronics.co.uk/shop/Speech_Synthesizer_SP032006.htm>

You can upload your own audio samples to it as well, which can be played back in anyway you so choose.

Maybe apocryphal but I heard that if you're stupid enough to look into an open waveguide of an active 10cm marine radar it would cause that eye to become the equivalent of a hard boiled egg. No need for a 3 minute timer then?

hello...

looking to build a simple (read cheap and small) even crude 28v 10amp switch mode psu to run on 240v in..have liiked on google etc but nothing found..
anyone know of any published designs..thanks simon g0zen..
please reply to group or zen@lineisp.co.uk..

thanks

Had big time Electric Shocks -- never fatal obviously
Had big time shocks that should (could) have been fatal -- ART- 13 Dynamotor
Navy. 440 AC - steel mill, etc.
But tis the current that does you in, not the voltage.

Coupla hundred milliAmperes will do it --- URL:
http://hypertextbook.com/facts/2000/JackHsu.shtml

Guess my Irish hide has lots of ohms!

Steel Mill Stories from the 40's (Maybe Urban Legend)

1. A lunch eater sat down and rested his head on a huge copper bus bar
(voltage unknown), someone turned on the switch, he was reduced to a
frazzled lump with a half a sandwich!

2. A careless electrician up high on an overhead crane, got across a high
voltage line and fell into one of those giant ladles that pour out the
molten steel. Not found.

Maybe the old steel mill hands -- told this to the new guys to scare the
hell out of em, Worked for me!

Lock the distribution box, take off all jewelry, keep one mitt behind you,
keep away from the chassis, -- all good advice, mostly learned the hard way.

Then there was a color TV High Voltage supply ---- ooccchhh !!! A teeth
rattling experience.

It also matters what the surface resistance of your skin is, and how
good a "connection" to the nervous system and heart.

For example, You could put dry fingers on a 9V battery and not feel a
thing, but if you lick your fingers first, get a real tingle. Same
voltage, but the moisture allows current to flow.

In medicine, the defibrillator paddles are covered with a conductive
gel, and use a precise pulse of voltage and current. In open heart
procedures, lower voltage and current is used, with paddles applied
directly to the heart.

Of course, disrupting the heart rhythm may happen with lower voltage,
especially AC or RF.

Why is being careful such a problem for some?

IIRC, field effect triodes {FETs} were made about the same time as the first
vacuum tubes, but they didn't work well enough, given materials technology
of the day.

I wrote of it before, so I'll be brief and hope I'm not boring. An open-coil hot plate with a ceramic holder to support and contain the nichrome element as filament*. Topped with galvanized window screening, the zinc removed with muriatic acid so as not to noxiously sublime, resting on the ceramic as (literally!) grid. Small glass beads -- around 1/16" -- scattered on it to create a gap and hold the screening flat. Atop that, a pie tin weighted with cooling water to serve as (literally!) plate. With 700 volts on the plate, I got measurable current on my 1000 ohm/volt meter. At -90 volts on the grid, the current was too small to read. The gain was enough to sustain oscillation.

The full version of OSHA-approved (the US Occupation Safety and Health
Administration of the Department of Labor) safety lock-out/tag-out
procedure includes safety procedures such as locking out the
electrical power to a piece of equipment while it is being worked on.

There is one device applied to the breaker box that locks it off, and
then each worker places their own personal padlock to keep that device
locked, as well as a supervisor and possibly a safety engineer. The
equipment cannot be turned on until every single person is finished
and has cleared the area.

Seems obsessive, but it doesn't produce stories like on this thread.

I thought that FETs dated to the early 30s. De Forest's "audion" was
invented in 1903 and made long-distance telephony practical by 1913.

Jerry

P.S. to Rick: That was before my time.

There are a few refs and calculations in
http://arXiv.org/pdf/physics/0102007

Lu, et al (referenced) found that peak power was
responsible for spark-gap transmitter injury in rats.

Microwave hearing (referenced somewhat; see a review
Supplement to Radio Science in 1977) also seems to be
because of peak, not average, power.

As a kid I wanted to test some light bulbs so I plugged a line cord
into the outlet and tried to touch the two bare wires to the
base of the bulb. I grabbed one bare conductor in each hand (ZAP!)
Oh the stupidity of youth! Luckly my hands were dry (no sweat!)
the house was air conditioned and humidity was very low.
I was able to quickly let go of the wires and pull the plug out of
the wall.

> lethal, but have forgotten.

No. It is actually quite hard to kill yourself with electrical shocks.
There are tons easier and more likely things to die from in everyday life.

60Hz AC is most dangerous in the range of 100 to 300 mA. Current in that
range sometimes causes ventricular fibrillation, whereas currents above that
usually cause the heart to temporarily contract and protect itself. Very
high currents, however, can dissipate lots of power in your organs and cook
them, leading to a painful death if nothing stops the electrocution for
several minutes. High frequency AC (like many kilohertz and beyond) should
be less dangerous since it will be bound by "skin effect" and not penetrate
as far into your chest cavity. DC is considerably safer than 60Hz AC, and
I've read some estimates saying you need 4 times as much current to die from
DC shocks. I don't know if I believe that though; I suspect there are too
few cases to draw significant statistical conclusions. As I understand it
(and I may be wrong here), DC is safer than AC because it doesn't cause
ventricular fibrillation, so death by these shocks occur from organ damage
and falling off ladders and things.

Howard Henry Schlunder

Too bad the old "B" batteries aren't common any more. As a 15 year
old (back in the prehistory of mankind) newcomer hobbyist to radio
and electronics, I couldn't feel anything across the snap-on terminals
of a 67 V "B" battery. Curious, I touched my tongue to them.

Z A P ! ! ! !

Stunned, I waited about a half hour to get my tongue unrolled.

Never EVER tried such a totally dumb idea again...

>In medicine, the defibrillator paddles are covered with a conductive

True enough. What is overlooked is that medical instruments,
meters, appliances are all precisely calibrated-adjusted-designed-
to-be-stable-in-their-settings...based on KNOWN INFORMATION to
medical and biological people.

>Of course, disrupting the heart rhythm may happen with lower voltage,
>especially AC or RF.
>
>Why is being careful such a problem for some?

Bravado and a general feeling of immortality. Especially true for males and once useful as a survival thing way back in time.

Some actually believe their boast "It can't happen to ME!" :-(

No problem for the morticians...keeps their business going.

The solid-state era was born with a dangerous side-effect: Low supply voltages. High voltages of 100 to 300 VDC weren't needed with transistors. Most folks are not able to feel supply voltages under 15 V, DC or AC. As a result they get way too CASUAL about handling supply rails with the power on. "Familiarity breeds contempt," etc.

When they take that casual attitude towards handling mains supplies with 115 to 230 VAC input, there's trouble just waiting to happen. It's like sticking one's hand into a snake basket...the snake may bite or it may not, depends on the snake...if it bites the bite can be deadly.

>then?

Back when I was doing electronic instrumentation with an optics group
at Rockwell, my first day in that group brought forth a caution from one
of the optical physicists about lasers: "Do NOT look INTO a laser beam
unless you want that to be the LAST thing you see."

That was with a little 10 milliWatt laser used on their optical table
for initial system calibration.

Good advice I thought...and remembered it.

I'm sure there are some in here who want to gabble about "open wave-
guide" and it "not radiating much because it is open, represents a
discontinuity, and the VSWR is so high there won't be any power
radiated." Which MIGHT happen at any microwave frequency from
L-band bottom (1 GHz) on up past Ku band (24 GHz+). That will
depend on the wavelength of the physical waveguide opening to the
microwave source. The magnetron MAY also refuse to oscillate due
to a high VSWR, flash over and trip its breaker or something to not
operate. Then again it MAY - with equal likelyhood - work just fine
with an opening and radiate FULL power out that open waveguide.
Or something in between full power and no power...a big unknown.

No matter how much anyone likes hardboiled eggs, those belong in
the mouth and not the eye sockets.

I found such a bulb in the loft of the garage of a house we were renting in the mid-1950s. I had read an article about them somewhere, so I took it inside, screwed it into a lamp near the TV, and, voila, instant Channel 3 TVI (that was the main channel in Milwaukee, WI, then). I put it in a box in my shack, and didn't think about it for some time.

I put up a tower and 20 meter beam. Before the coax was in the house, a neighbor sent his kid over to complain about TVI. I invited him to come over and see that the TV in my shack was not showing any interference, but he declined, and continued to complain over the next few months.

While preparing to leave for two weeks vacation, I had a flash of inspiration. I put the bulb in a lamp, connected a timer to the lamp, and put it in a closet (so the light couldn't be seen in an otherwise dark house). The timer turned the bulb on during evening TV hours.

I left it on for several days after our return. The neighbor never complained of TVI again.

Yeah, it's been like that for at least 15 years. Anti-static work mats
aren't conductive either. So what principle do they use?

Actually, they ARE supposed to be conductive- at least to the tune of about a megohm. In any operation that is serious about antistatic procedures, the mats, wrist straps, and other equipment are to be tested periodically. Most testers show if a mat reads open right away.
If you have mats or other equipment that read open, then you have found defective hardware. Trash it.

"I just got this setup and the it seems to work OK except the that the
DISPLAY UNCAL lamp on the 8553B doesn't light when it should."

I don't know why, but I just happen to have a 8553B manual on my desk.
The UNCAL light (according to the parts list) is 12V 0.06A. The wiring
to it comes from the Bandwidth & Scan width switches via the IF section
(which I don't have a manual for). It is very very complicated! (I lost
count of the number of manual pages it covered;-)

Ps: Wish I had the analyser, not just one of he manuals.

Well, I got hit by lightening while camping in the mountains as a kid. I was laying down in my "fern" bed on the ground in my pup tent. The ground liquidified like a wave, first raising my head, then lowering, and then my hips, then feet raised and lowered.

Took about 3 minutes for my eyesight to come back, about 8 or 10 minutes for any hearing. I didn't like being blind for 3 minutes alone out in a tent in bear country!

Another time as a kid, my Aunt Katherine had one of the old, old electric fence units that used a light bulb to limit the current. She put a big wattage bulb in there, to really shock the cows, as they were ignoring the regular shocks. I was out in the field, and as a kid, tried to see how high I could pee. I didn't realize the electric fence wire went thru the other side of that huge bush.

Yep, you got it--- with a body being 90% water, it went up into me, and all over my body internally. Threw me down on the ground, I saw huge Black stars (daytime), muscle contraction from electric shock, I was peeing straight upwards out of control, since I was on my back on the ground, it all came down like a fountain above me, all over me. It took years before I told this story (the other guy had it happen to him too).

Then in the Navy I got about 20 KV of RF which burned a hole clear through my finger. I could've fed a thread through my finger. Took a long time to grow together.

And, yes, I remember discharging the Radar Caps with that long grounding stick with the wood handle. Never got shocked there, just good and scared.

I got caught in front of a radar antenna (20 feet) that someone had turned on. I had my back to it, I got very sweaty and hot, turned around, and it was rotating. I've had problems with uncontrolled sweating since that day in 1958. I soak the pillow every night, my clothes everyday. To this day.

I'm thinking of changing my name to "Lucky" :-)
I've learmed to laugh at myself.
Seems everytime some Doggoned thing comes along, my Creator seems to say "Let's try this on Ron, He really gives ME a lotta laughs".

Best to all---
Ron a Scot :-)
Lucky

Armco (now A-K) Steel in Middletown Ohio supposedly had a man (who was upset over his wife cheating on him) commit suicide by jumping into one of the soaking pits were they heat the ingots before it is rolled into sheet metal.

The country artist, Tom T. Hall, wrote and recorded a song called, "The rolling mills of Middletown" about it. The company was going to sue him over it, but they never did.

A friend of mine who worked there told me they had a big problem with the old vending machines, and the company that owned them refused to maintain them. Someone on night shift lost his last quarter in a Coke machine so he got back on his fork lift, rammed the forks through the machine, and dumped it into one of the empty soaking pits to watch it melt.

I recall having read that AC is considerably more dangerous, for the reason that Howard stated. Furthermore, 60 Hz is just about the worst frequency. This was determined by executing dogs in less enlightened times. I've also read that Edison created and promoted the electric chair, which was run from AC, to dramatize the danger of AC over DC. He had a big investment in DC distribution systems and equipment, while Westinghouse was promoting AC power distribution.

Actually, I should have said a megohm for a ground strap and 10 megohms or so per square for mats. Since they are by area and not linear, the specification has to be per square.

Cheers!

Thanks guys.

John, the sci.electronics.repair folks didn't have anything to say about it
:-(

Someone else thought the series LC from the driver transistor's emiter to
ground might be a "colour killer" and putting a notch in the frequency
response of the driver at about the same frequency my 320 pixels are at
(4MHz). I tried shorting the L altogether and there was no visible
difference on the display. That same person also mentioned gamma of the
tube, but I don't know much about that. I would find it hard to believe that
the tube itself was the limitation here, it must be the video driver.

Interestingly the fading at the top of the screen dissappears when the
"brightness" control is turned up, but that makes the bulging noise floor
worse and also dims thin vertical lines even more. Arrgh.

Didn't Edison try to get execution by electric chair "Westinghousing"
too, or is that a rumour.

BTW, on the subject of anti-static that measures open, some of these
are one-sided. That is, some bags are metal film coated on the
inside, so across the outside they will read open.

Doug -

Replacement capacitors are available from Mouser Electronics.

Jeff Weinberg at Harbach Electronics also carries a number of parts for the
SB-220 as well as
electrolytic capacitors. (See CAPS and SB-220 reference on left frame)

The simplest way I know to do this provides an unregulated output,
much as a mains-frequency transformer coupled supply. The advantages
are that it is much more compact and lower cost. By not using
feedback regulation, you avoid stability issues and some complexity.
One of the size and cost factors is that electrolytic caps of a given
physical size hold more energy for a 250 volt rating than for a 50V
rating. The idea is simple: just bridge-rectify the mains, feeding a
large storage capacitance. It's probably easiest to use two large
250V caps in series, with balancing/bleeder resistors across them.
Put two 1uF or more polypropylene caps in series across the HV (300V?)
DC. Transformer primary connects to the center-tap of the polyprop
caps. Other side of transformer primary is driven by a half-bridge of
power mosfets, which are driven by a self-oscillating half-bridge
driver such as the IR2153. The primary will then be driven with a
square wave, and the driver is designed to prevent overlap and handle
the high-voltage offset of the "upper" mosfet. Just rectify the
secondary (with Schottky diodes if you can get ones with high enough
voltage rating, or with ultra-fast non-Schottkys) and put a bit of
filtering on it, and you have your unregulated 28V (or other voltage,
if you wish). Add a power-factor corrector/preregulator on the front
end and you have a semi-regulated output. Design of the transformer
is left as an exercise...but isn't overwhelming and doesn't require a
lot of turns, generally.

Cheers,
Tom

1200. Q-Meter

I had some ferrite cores in a envelope marked FT50-43. To check that these cores are actually FT50-43, I put a test winding on one and calculated the inductance. Using a Booton 260A Q-Meter, I tried to verify this. I got no indication over a wide frequency range on the Q-Meter. The Q-Meter stayed at zero.

Doing the same thing with a FT50-61 core, the Q-Meter gave a accurate indication. Is there something about the 43 material that does not allow a indication on the Q-Meter?

The sign I saw in the crystallography lab at ou.edu was very simple:

Caution: Do not look into laser beam with remaining eye.

That was something like a 150W Argon laser.

An acquaintance was working on some plumbing Saturday in one of several houses under construction in a new subdivision in Albuquerque (New Mexico), and there was a lightning strike into another of the houses, a few hundred feet away. He told me he got knocked flat and so did his helper.

Albq is, as many will know, in high desert country, and the ground is *anything* but wet, so buried pipes aren't particularly useful as earth ground. This is a pretty good illustration of that.

Source record: 33323

Depends on the frequency. The Q of type 43 ferrite is 1 at a few MHz,
and less than 1 above that. It's unlikely that your Boonton will measure
Q that low. You'd be able to measure a decent Q at a few tens of kHz if
the meter goes that low.

The low Q is fine for broadband transformers and definitely a good thing
for RF suppression (one of the primary markets for type 43 material).
But you wouldn't want to make a tuned circuit inductor out of it at HF.

See http://www.fair-rite.com for more information about the frequency
characteristics of various types of ferrites.

=================
Suggest you try to recondition (reform) the existing electrolytic caps
before replacing them .

Remove wiring from caps and charge them individually slowly via a 1or 2 Watt
, 47 KOhms resistor to the rated working voltage .
It is possible that in the first round you won't achieve that . When voltage
across cap no longer increases ,discharge via the same resistor . Charge
again ; the end voltage will be higher. Then discharge again.
When upon charging the caps voltage no longer increases measure the voltage
across the known resistor to determine the leak current. It might be
worthwhile to repeat the charge/discharge process a few times.

In the above way I have this week reconditioned a variety of electrolytic
caps the largest being 1000 microFarad -450 V.
Although the Working Voltage for this particular cap (of which I have 8 pcs)
is 450 V ,they happily accept a charge to a voltage of 510 V with an overall
supply of 550 V , hence 40 V across the 47 kOhms series resistor ,hence the
leak current is less than 1 mA.
Some old Plessey capacitors from 1974 , 200 microFarad - 450 V have
successfully received the same treatment.
I now intend to check the effectiveness by placing the caps (1 at the time)
across the output terminals of a power supply unit made from a suitable
transformer and half wave rectifier watching the voltage output wave form on
a scope at varying load.

For lower voltage electrolytic caps smaller series resistors are required .

The caps should be slowly charged /discharged ,each operation taking about
4 - 5 minutes.

http://www.fairradio.com/variac.htm has a few dial plates for Variacs, and they're pretty cheap. You may have to call or email them for their latest stock. I bought a few from them a couple months ago, and they were in new, unused condition.
Cheers!!

Roy is correct, the Q is too low to register on a Boonton 260A Q-meter
or, for that matter, on the 4342A Q meter. I've had success, however,
measuring coils wound on Type 43 material with both the GenRad 916 RF
bridge and a Boonton 250 RX meter. In both cases, you are measuring
R+jX of the inductor, so you can then go back and calculate the Q.
(Series with the 916 bridge, parallel with the 250 RX meter, so you
may have to do a little extra math if you take the data with the 250
RX meter.)

(I was measuring leakage and magnetizing inductance of some broadband
transformers I wound.)

Take two pc type SPS and run the outputs in series, most have a input select
for 110/220 vac.
It sounds strange, but from what I have found, if the supplies are identical
it will work fine.
It's cheap easy and lots of spares to choose from.

Some PC power supplies might have the 0 V DC connected to the chassis,
so putting them directly in series would require isolating the power
supplies from each other. Unfortunately, this is not possible, if you
want to properly connect the power supplies to a grounded mains
socket.

You musty disconnect the 0 V DC side (and any other circuitry on the
secondary side of the transformer) from the chassis if you want to
connect the power supplies in series. By doing this, the chassis of
each power supply can be safely connected to the mains ground.

You can make your own in Photoshop and print on some of the clear films
that have adhesive on one side-as in
http://www.chartpak.com/kohinoor/2surfaces/index.html
or water slip decals like:
http://www.supercaldecals.com/water-slip-decals1.html

I have made complex freq dials using these techniques.

Source record: 33335

Roy et al:

I've always wondered why no one ever tries to use the constant resistance LC lattice all-pass
networks to make variable phase [delay] networks for HF antennas.

In the simplest LC all-pass lattice there are two matching inductors in the "through"
arms and two matchng capacitors in the "cross" arms. [Or an equivalent version with two
"through" capacitors and two "cross" inductors.]

When terminated in it's designed constant resistance R such a network also has a constant
input driving point impedance of R.

In practice, the transfer function of the LC constant resistance lattice network has a flat magnitude
over very wide frequency ranges, and twice the phase shift characteristic of a single LC network.

Potentially the phase shift could be made variable by mechanically or electrically
ganging the two "cross" capacitors together so that they could be tuned in synchronism
to continuously vary the phase shift while maintaining the constant driving point
impedance/resistance. Or vice versa, the inductors could be ganged.

For some range of pole-zero locations the full lattice can be unbalanced into a bridged-Tee
network which is perhaps easier to tune than the lattice. Indeed the transformer assisted
half-lattice is also a candidate with easier tuning.

Good information on LC lattice networks is available in the "older" network synthesis litterature.

cfr:

Louis Weinberg, "Network Analysis and Synthesis", McGraw-Hill, New York, 1962.
Shelved at you technical library under LC Shelf Call TK3226.W395

or...

Ernst A. Guillemin, "Synthesis of Passive Networks", John Wiley, New York, 1957.

Shelved at LC Shelf Call TK3226.G84 or Dewey 621.319.

For some reason folks interested in phasing antennas have not seemed to be interested
in the constant resistance all-pass LC networks. I don't know why? They seem to meet
all of the relavent requirements. i.e. a constant resistive driving point impedance, and a
potential of continuous 360 degree variable phase, while maintaining the constant driving
point impedance.

On EBay, the Power-One International Series of 24 Volt switchers will handle wide input ranges. It would just be a matter of tweaking the regulator detect circuit -- I don't even think it would require adjusting the compensation. These supplies typically sell for under $40. There is a power supply section under test and measurement. Cheaper to buy than build.

If you are in the U.S., review FCC rules under part 15.217 governing
operation within the 160-190 kHz band (yes it's kHz). Reliable 100
mile range is possible is some areas at limited information rates. I'm
not sure if remote control is allowed.

It would want to be a fairly large robot to accommodate an efficient antenna system at that freq, and esp if Tx was contemplated.

Twice:
1) Working on a portable battery-operated 120vac source. (My own design). Got each hand on the 120vac while
wearing the device. Could not breath; could not yell for help. Saved myself by intentionally falling onto
the battery pack and luckly broke the pack apart.

2) Working on the HV of a 1KW transmitter. Power was off, but caught the 4KV from the filter capacitors.
Threw me across the room. Guess my heart was healthy enough to recover a normal beat.

AC is more dangerous for two reasons. It causes muscle to contract and not release, so you cannot let go,
and at 50 or 60Hz it is likely to fibrilate the heart. A single jolt of DC, if it does not damage too much
tissue, will tend to leave the heart in a (properly) synchronized state so it can resume a normal beat.

I can explain the physiology in detail if someone is interested.

I would agree except for RF. RF can punch a hole through tissue, leaving a burn through the path. If your
vital organ is in the path it gets cauterized. If you hit a key spot, like the AV node of the heart or
along the Bundle of His, you are in trouble.

: > lethal, but have forgotten.
:
: No. It is actually quite hard to kill yourself with electrical shocks.
: There are tons easier and more likely things to die from in everyday life.
:
: 60Hz AC is most dangerous in the range of 100 to 300 mA. Current in that
: range sometimes causes ventricular fibrillation, whereas currents above that
: usually cause the heart to temporarily contract and protect itself. Very
: high currents, however, can dissipate lots of power in your organs and cook
: them, leading to a painful death if nothing stops the electrocution for
: several minutes. High frequency AC (like many kilohertz and beyond) should
: be less dangerous since it will be bound by "skin effect" and not penetrate
: as far into your chest cavity. DC is considerably safer than 60Hz AC, and
: I've read some estimates saying you need 4 times as much current to die from
: DC shocks. I don't know if I believe that though; I suspect there are too
: few cases to draw significant statistical conclusions. As I understand it
: (and I may be wrong here), DC is safer than AC because it doesn't cause
: ventricular fibrillation, so death by these shocks occur from organ damage
: and falling off ladders and things.
:
: Howard Henry Schlunder

Twisting the thread a little:

I worked with an engineer who was very proud of his floating high-voltage AC plasma display sustainer drive circuit. Since it was floating, you could touch any part and not get a shock (or upset the display, either). He showed my by touching the cases of a few of the power transistors in turn. Then he jerked his hand back and let out a yell.

Instant second-degree-burn blister.

this link was in today's New York Times --

www.microsoft.com/security/incident/blast.asp

It details the ways in which you can avoid being hacked by this new bug.

I point it out since we have had a series of bugs relating to MSOffice functions here in recent days. The Atlanta Federal Reserve and Maryland DMV had to shut down operations due to the bug.

Indeed it would be a large Tx antenna; however, the receiver I built
in 1974 had a ferrite rod antenna, measuring about 3 inches long,
IIRC. We received a clear audio (AM) signal above the noise from in
Detroit, Michigan from Cleveland, Ohio. The antenna at the transmitter
was 48 feet vertical suspended from fishing line between two oaks. If
Tx from a robot were required, a VHF to Longwave relay link should do
the trick.

To integrate a PIC controller with a transceiver, you would choose a transceiver that supports computer control. Most recent transceivers can be controlled via an asynchronous bit-serial protocol; some use RS232, and others use TTL that can be level-shifted to RS232. Generally, the protocol is described in the user manual. If you were choosing a transceiver solely on the basis of the control capability, you would look closely at the Icom 703 (or whatever the most recent model 706 is called -- MKIIG is it?) or perhaps the Yaesu 817/857 family. The Kenwood TS2000 provides full control using a clean protocol, but may be a physically a bit large for your application; I've never looked at the TS50's command set, and so can't comment on its applicability.

Obviously power, volume, and weight budgets will have an impact on your decision, as will your choice of frequencies.

73,

Dave, AA6YQ

I second that.

I've been having DSL trouble recently, and was doing some troubleshooting with my ISP. Since the normal DSL connection wasn't working anyway, I disabled my firewall to make it possible for the ISP to ping me. Later, having forgotten that my firewall was off, I connected to the web with a dialup connection. Less than 5 minutes into the session, I got a notice that my system was shutting down due to something relating to "RPC". When I rebooted the firewall loaded automatically and caught "msblast.exe" trying to contact the Internet.

So it took less than 5 minutes on a dialup connection without a firewall to get nabbed.

Msblast.exe, as it turns out, emails MS in an attempt to bog down its site and make it difficult or impossible for people to download the security patch MS has developed.

You'll find more good information, and a virus remover, at http://securityresponse.symantec.com/avcenter/venc/data/w32.blaster.worm.html.

I was able to download the MS patch in spite of its getting blasted.

No doubt this is an easy question, but is there a way of interfacing to the web via HF SSB/data?
I want to be able to do this from a remote location portable/backpack with no mobile phone access and low power. The nearest infrastructure could be several hundred km away
I could use amateur bands or possibly a commercial solution if available.
What would be the data format and where would I get more info on this?

Thanks
Richard

YOu can probably forget any amateur solution. I think 300 baud is the max
for the low bands and not much beter for most other bands. YOu might be
able to read your email if you do not get any spam before the trip is over.

You can do e-mail via Pactor on HF. On the ham bands you need to screen the content and that pretty much leaves out web surfing - not to mention the slow data rates. I believe the e-mail is limited to the users you give access to so you don't have to worry about spam. This site will probably give you the information you need: http://www.airmail2000.com/

Eh? Is this humour? UK household mains is 240V ac (235V ac now but the tolerance band includes 240V so it many places is stayed the same AFAIK). The lines are E (Earth, Green/yellow), Neutral (blue), Live (brown, fused). E and N are at same potential, as is metalwork in the house. L is 235V ac. So if you are holding L and it is on your house is wired wrong, or you are Mr Rubber man.

FYI (non UK'ers) the common arrangement is called PME, Protective Multiple Earth. The N line is bonded to earth (via the underground cabling AFAIR). N is thus at low potential near earth. At the company incoming fuse box the N line is split to E and N. The customer gets E, N, and L wires. The E terminal is bonded to all metal work, baths, plumbing etc. Hence you cannot get a shock from N to E. Switches tend to be single pole in the L as switching L and N would be dangerous if just N failed. You do get double pole so they must have a fail safe scheme for those. Fusing is only in the L for the same reason.

Richard,

If you knew the regs you'd know that this is illegal on the ham bands.
The only legit way is via a WiPoP which is short range and would require
infrastructure in your area of interest. Skip it.

Rob

When I was 14 I used to open an old tube TV,
then I put one hand on the high-voltage tube
that goes to the anode of the TV screen.
There are a few thousand volts here, and I
remember perfectly the two inches spark that went
to my hand before I actually touch the tube.

Fortunately the power is low, and the maximal current
shoud be roughly one mA, or else I wouldn't write it now !

But of course, if you're in Tucson this doesn't apply. :)

There are FCC regs forbidding it too, but there are evidently loopholes
in the US. None here in Australia though, which is where the question
originated.

This shoulds like a job for a satellite. If worst comes
to worst, plug a modem in to a satellite phone and dial
up your ISP...

The first UoSATs were for exactly this sort of application:
take a briefcase-sized station in to the field and send
chitchat back to home base by satellite, completely
independent of terrestrial infrastructure, which may not
exist anyway.

We have satellite Internet here in Canada. It isn't cheap.

Hi all,
I am having a spot of bother with prescaler chips. Basically I need to find one at the right price and availability. US$5 each is reasonable, but where from? Is there one available that is not obsolete?

I live in Sweden and my local component shop is ELFA (Swedens answer to RS). They don't sell ANY digital divider that operates above 50MHz, except for the 74F163 and I cannot come up with a reliable interface circuit to couple an oscillator into it at over 100MHz.

I found the MB501 (MC12022, SP8704) but it is obsolete and cannot find a reliable source. I bought a couple, but that source dried up. All I need is a divider chip that will accept a small signal up to 150MHz, is available, cheap(ish) and will divide down to under 10MHz so that I can use CMOS to process a synthesiser. A parallel-load synthesiser chip with in-built 150MHz prescaler would do.

I have used "Teleport" to download over 50,000 pdf datasheets without any luck. I have gone through most of them, but it takes a fair bit of time. If anyone has a helpful suggestion I would appreciate it.

The problems with a satellite solution are cost, weight and power. I want to be able to carry the whole thing backpack for several hundred km and for it to operate on battery power. There is a commercial HF SSB station in Sydney for marine radio - it looks like I would be using this if I was in the eastern states of Australia (ultimately I want to do an extended trek along the Vic/NSW alpine trail). This is mainly remote mountainous country with occasional 4WD tracks and roads and very few settlements. I have loked at the SSB radio options - the best seems to be the SCS transceiver, but Rx current is still> 100mA.
I would probably use a PalmPilot as the computer part with an interface to this. Here in WA there doesnt seem to be any options (we are 3000km from the eastern seaboard). All in all a big project!

Richard

I'm aware of a service that provides e-mail on commercial HF frequencies to
safari camps in Botswana from a base in Johannesburg in South Africa. AFAIK
they use Pactor. Many of these camps are several hundred miles from the
nearest phone line.
(My cousin worked in some of the camps)

Have you considered adding a solar cell or two the station. I am using a much smaller radio, but a 15 watt cell has me battery independent. A 1.4 watt cell maintained enough charge on the gel-cell for me to operate field day weekend.

Man, if THIS ain't a trip -- a well-known, over-rated internet homebrew tech
asking for help for a simple prescaler. Hey Harry, don't you know that the basic
freshman-lab-grade Class B or C amplifier is nothing more than a divide-by-2
counter? If you have a bunch of 2N2222's, 2N2907's, or any transistor with an Ft
above your high-freq limit, you have a divide-by-(n x 2) counter. Any advanced
homebrewer should know that stuff cause it's basic theory.

And for you to post such a question in alt.radio.pirate.... that's pretty
pathetic, Harry.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday August 17th 2003
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

If you can live with a larger and binary division, there would be
a prescaler that likely does work to that frequency limit in any
digitally tuned FM broadcast radio. I have not looked up the
upper frequency limit on these, but of course their needed range
isn't much lower than your upper limit. I don't have a specific
part number, I'm not even sure how much variety of ICs are used
in these applications, but just about any scrap digitally tuned
radio would offer up something. And if you need to find something
commonly available but not rely on scrounging, then open one
up and find the NTE replacement for the prescaler.

Hi,

Can anyone find the spec or equivalent for a mullard YL1321, looks like the same pinout as the
4cx250/350 family but conduction cooled. The main concern is the heater voltage, usually 6.3 or
26.5. I have tried the usual google etc and its not in any of my data books.

Thanks,

Steve H.

I found an Archer "Wireless Oscillator" in my parts box. It was sold by Radio Shack some years back, part number 277-237. I would like a datasheet and schematics on it's use. I can't find anything using Google. Hopefully, this will be the item I need to create a wireless AM broadcaster so I can use it as a baby monitor or listen to my MP3's while out working in the garden. (At least I assume that that is what this is used for.) It has 6 pins on the bottom, 3 on each end.

I would appreciate any information anyone can provide on this item.

Ultimately, I'd like to be able to broadcast old time recordings to actively display an old AM radio I am restoring.

I'd be inclined to use a CPLD. The Xilinx XC9536 would be good to over 150
MHz and a suitable synchronous counter is quite trivial.

Laura,

We can only get a sat downlink here easily. The uplink is almost always
a dialup.

Rob

Hi,

They are listed at -

http://www.mouser.com/catalog/615/217.pdf

and NEC have a data sheet on-line if you do a quick Google.

I should point out that they are really only simple dividers
with none of the front-end bits necessary to make a complete
prescaler. I was thinking of using one with an old Racal 1991 VHF
counter that has the built-in maths capability required to enable
a non-decade pre-division.

Cheers - Joe

Does this mean that I died on the operating table during my
open heart surgery last year, and awoke in a different reality
where I am still living?

Early electric chairs WERE AC, but they tended to fry you rather than
electrocute. But at high frequency AC isn't as dangerous as DC.
Tesla used to demonstrate passing a million volts through his body to
light gas tubes, but he used high frequency current (in the khz range) to
do it.

Talk to any pro music store that works on tube guitar amps. That kind of
cap is real common for power supply filter capacitors.

>Early electric chairs WERE AC, but they tended to fry you rather than
>electrocute.

Electric chairs, early and semi-modern and modern, use/used AC because AC electrocutes more than DC does (at least if the AC frequency is in the power-line, lower-audio or upper-"subsonic" frequency range). (AC frequencies of radio frequencies or high audio frequencies were safer.)

This business of electric chairs frying rather than electrocuting has a grain of truth - electric chairs often have enough voltage and current to cook vital organs in case "more-true electrocution" does not occur.

Electrocution in a typical case is most likely with AC (secondarily pulsating DC) of power line or lower-audio or nearly-audio-subaudio frequency and with shock path involving the head or a limb so as to involve the brain or the heart or both. Worst case usually involves ventricular fibrillation, a deadly disturbance in heart rhythm where electrical cause is "typically" 100-1,000 mA of low frequency AC or pulsating DC through the torso.
Electrocution is unreliable enough that electric chairs require "backup" mechanisms of killing. As in either cooking vital organs or paralyzing breating long enough to deprive the brain of oxygen long enough to disable restarting of breathing when the shock is stopped. I insist that survival of shocks that are not far from bad-case is equally unreliable!

>Tesla used to demonstrate passing a million volts through his body to
>light gas tubes, but he used high frequency current (in the khz range) to
>do it.

Tesla-related AC survival involved high frequencies that are not as bad as either lower frequency AC or unsteady DC! High enough frequency AC is less-electrocuting than DC can be given even slowest accidental

application/removal rates!
Horror stories by horrifically-burned high-voltage-DC survivors come mainly from those who lived to tell a horrific tale rather than had a closed-casket funeral because the current was DC rather than power-line-frequency AC.

Source record: 33295

I have thought about using one of the modern SM PLL chips such as the National LMX2326 which can be progammed to give any division over a wide range (you do need a controller though to drive it) - you can access the main divider output directly and ignore the phase divider. These are widely available and pretty cheap. I would think you could do one one these "dead bug" with care, though they are SSOP. Of course if you are doing a PLL, why not use the whole chip?

Put 6.0 (not 6.3)V on the heater pins and see if it draws the right sort of
current - if it's a higher voltage version, you won't do any harm. I don't
know of any variants that ran at lower voltage.

Did the surgeons tell you they'd lost you for a while there? If so,
you might have been revived in that same reality in the usual way, or
else if such efforts failed, you'd then 'come round' in one of the
other remaining universes in which you didn't die, in an example the
so-called 'weak anthropic principle.'

Not available in Sweden, just the usual 300MHz unity-gain (BC547, 557, etc), and the circuit stops operating at about 100MHz when the gain/pcb has become useless. I need RF transistors that are not available. ELFA only have no RF small signal devices.

> And for you to post such a question in alt.radio.pirate.... that's pretty

I was a pirate myself, LONG before I became an amateur. I have a lot of respect for the knowledge and experience of some of these so-called "pirates". I wonder how just many "pirates" you have spoken to on the HF bands? Certainly more than 0 and you were not even aware of it.

Jonesy is correct. Actually, I'm not familiar with this exact model klystron, but have worked with a lot of very similar ones used as the local oscillator for marine radar receivers. The base pin arrangement, which is an obvious "octal" base scheme variation includes one extra long pin. You can see it in the photographs. That pin is the klystron oscillator's output. It is actually a radiating "probe", sort of an antenna that protrudes right into a microwave "cavity". The 2K25 or RK25 was a common WWII surplus item that Ham experimenters used as an "X" band RF source. It's output frequency was a little higher than 9ghz if memory serves me right, and could directly feed a microwave "horn" antenna for transmission. It is tuned in two ways. Coarse tuning was done by turning a square headed screw on the "grasshopper", the outboard metal junk hanging on the side of the metal envelope. Fine tuning was by adjusting the voltage on the top cap. Cathode?? Oh, yeah, the tool used to coarse tune this little hummer must be insulated. Lethal (or nearly lethal, in my case) voltage is right on that blasted square headed screw.

And if memory serves me correctly it is negative voltage with respect to the cathode. Feedback necessary to sustain oscillation if accomplished by running electrons back and forth through the tube to place in phase shocks to the resonate cavity in the tube.

Out of curiosity, how do you know that they're FETs?? They could easily be
BJT's SCRs, TRIACS, or just about any other type of semiconductor that has
been produced in that package.

My surgery was actually 'text book', but my recovery was a little rocky. My lungs filled with fluid and I was moved back into intensive care a day after being put in a normal recovery room after the surgery. I was on 100% O2 for a day or so, after they inserted a needle in my back and drained the fluid (about a liter or two) I was much better. I was seeing things because of the drugs I was on though. When ever I closed my eyes I felt like I was floating in a crypt and I saw gargoyles on the walls with red eyes. They gave me something to help me relax and then the vision changed....I was now floating in a toy work shop (north pole?) surrounded by dolls and wooden toys and model trains. The visions disappeared when I was taken off the O2.

what frequency steps are you looking for harry????
if its for the broadcast band then the philips range of tsa5511/12/14 are
cheap and have upper operating range of 1300mhz, only trouble with them is
50khz steps..pic codes available on the net...otherwise the mc 145170 is a
good choice, operates up to 170mhz..but is serial controlled as well....

thanks for info peoples.....

2x12v computer psu is interesting but takes up too much space....
now i have more info i will try using the parts from a computer psu but with modified/own stepdown transformer...going this way as it will be cheap..ie ex psu costs 3gbp so if i kill it then so what!!

I assume the transformer will be similar just with twice (ish) the amount of windings on the sec.and that i will have to add some R in the feedback crt so that the pwm chip still sees 2.5v(ish) and prehaps remove the scr overvoltage protection..OR i will make it unregulated.

will let you know in due course case someone out there is interested.

Most applications (not Hams) grounded the tube shell and ran about minus 250
-300
volt on the filament / cathode and a variable minus 75 to 150 on the repeller
(cap). the
repeller voltage was reference to the cathode so it ran minus 325 to 450 volts
reference
to ground.

I have a couple of these in my junk box and used one many years back

Find out which winding is used for feedback/regulation, and leave it
alone - or consider replacing it with lighter gauge wire to obtain
more core cross-section for your 28V winding.

Also, if an AT type, usually the +5V winding requires a base load.

You can remove the -5v and -12V windings.

>you simply site there and ridicule people.

My point was that the art of homebrewing loses something when it's reduced to just plugging in a chip. Seems like everyone is ignoring how the circuits work and taking the 'black-box' approach instead. For example, the MAX038 is a chip that is a ready-made 0-20 MHz function generator with sweep, variable duty cycle, frequency modulation, and a phase discriminator. I'm sure that sounds cool to some, but if all you need is a 100 kHz square wave, why not learn how to build a square-wave oscillator with one or two transistors? And if you want a function generator, where's the fun in just hooking up power to a chip? That's not homebrewing, at least not in my book.

Do you need a prescaler that's fast enough to get the freq down to chip-speed? Try a simple flip-flop. Two transistors, that's all. There are probably a few dozen schematics on the net and dozens more at the public library (you do have public libraries in Sweden, don't you?).

>> ... over-rated ...

>small signal devices.

They don't have VHF or UHF in Sweden? Scrap a few FM radios and I'm sure you can find some MPSA10's and/or their equivalent. Regardless, an astable multivibrator doesn't need much gain to work. And when it's built with discrete components it's about the best prescaler you can have -- takes up about as much space as a chip, uses less power, costs a lot less, and is more flexible in terms of the power supply and input signal levels. Since you probably only need a stage or two to get the freq down to the input speed of a ripple counter, a simple flip-flop is almost the ideal circuit.

>> And for you to post such a question in alt.radio.pirate.... that's pretty
>> pathetic, Harry.

Hi,I am student & curiously want to build a practical ,high frequency spectrum analyzer , I have searched a lot for a one such : GBPPR 0 - 1000 MHz Spectrum Analyzer,
A Spectrum Analyzer for the Radio Amateur By Wes Hayward, W7ZOI, and Terry White, K7TAU & some others ï¿½, according that I live in iran I have some restrictions a bout some parts that they use in their circuits , but I think may poor mans spectrum analyzer is a good chaos because always I can find tv tuner as mixer , I think about four times I have emailed to MURRAY BARLOWE, WA2PZO
(radioguy@hoflink.com) the owner of home page of poormans sa on www.science-workshop.com (Updated 2/26/2003) but he doesn't answare ! has anyone buy recently from it ? does any one see the book or CD of "BUILD YOUR SPECTRUM ANALYZER " THAT IS SELLED ON HIS HOMEPAGE?
I DON'T WANT TO BUY THE KIT , I WANT TO BUY THE book or CD & according to the circuits & the parts I can find here make it,so does that book indicate circuits in detail or only say how do the kits should be connected together ? if so where can I found the circuit of it ?
Any help would be most appreciated.
Payam
Can you email me for reply instead of answering on group ?
payam79b@yahoo.com
thanks

Interesting. Most people who undergo NDEs report a heavenly experience
that often changes their outlook on life everafter. However, there are
a *small* proportion of NDEs where the subjects report a truly hellish
experience very much worse than you have described. Anyway, that's not
what I was getting at, of course.
I should also point out that the theoretical physicists have not thus
far extended the Quantum Theory of Immortality to encompass anything
beyond *instant* death; the orginal example by Tegal in his Quantum
Suicide Experiment was that of being shot in the head. I don't see any
reason why it should not be so extended to more protracted deaths, and
thinking among those involved in formulating this line of argument is
heading that way, but I'm no quantum pysicist so anyone curious should
follow up the leads I gave earlier in the thread and read up for
themselves.

Harris poll results reported in the July/August issue of _Skeptical Inquirer_ reveal that 84% of Americans believe in survival of the soul after death. 82% believe there's a heaven, and 63% expect to go there. But while 69% believe in hell, only 1% expect to go there. Wonder if the "small" proportion happens to be about 1%. . . and wonder if it's the same ones.

I'm trying to find a way to measure the capacity of single -- mainly AA -- batteries. Some of my battery packs don't last as long as they should because of mismatches in cell capacity.

I've got a good assortment of electronic equipment, variable power supplies, high power resistors, etc. I've even got a Maha MH-C777PLUS charger/discharger. But this doesn't let you do single cells.

I can come up with some -- not so great -- ways to measure capacity, like discharging thru a resistor while monitoring voltage. This would allow me to at least match batteries somewhat but not really measure true capacity. For true capacity I need a constant current device, and that's where I'm stumped.

This could be electronic, if it's inexpensive and I can get the parts at Radio Shack. But I'm thinking more along the lines of a mechanical device to drain the battery in a constant current fashion. An electric motor would just slow down, so that wouln't work. What type of mechanical device pulls a constant current regardless of input voltage?

Does anyone have any suggestions on how to do this?

Thanks for your help.

You can use a 3 terminal voltage regulator and a resistor or two. They can
be wired for a constant current generator instead of constant voltage.

Open it up, and see what's in side. It will likely be one of two routes.
Either it's going to have a lot of TTL, a decade counter/latch/decoder
for each digit (and possibly 7490/7475/7447), and a divider chain made
up of a string of decade counters. Or it's going to have a large IC that
does all or most of the work, something like the Intersil 7208.

If it's the first case, you can look up any schematic from 20 to 30
years ago, and get the basic wiring. There may be small changes
but it will be fairly constant. Or pull out a TTL databook, and you
will get the functions of the pins. The real variation will be on
the input circuity, ie the analog stuff before it's converted
to TTL, and the reset circuitry.

If it's a large IC inside, then find the datasheet and again
you will have most of the schematic. There will be much less variation
in this case, since the wiring is pretty fixed.

Once you have this basic information, then you can trace to find out
what's not working. Figure out the time base, and make sure it's
outputing properly. Maybe in either case, the analog circuitry is
at fault (after all, it faces an uncontrolled environment, when it's
hooked up to outside circuitry), you can always feed its output
with a TTL oscillator in the HF range, in effect inject a signal,
and if the counter reads out the right frequency, you know where
the problem lies.

Put an AMP meter across the battery. A "AA" should be good
for about 1.2 amps or so. Make sure the multi meter is in
the 10 amp position before you do this!

Good luck, John w5cgu

That was going to be my suggestion, for a split second. Then I
realised the Vin-Vout differential wouldn't let this work on a single
AA.

You don't need a constant current sink to determine "true" capacity.
If your load resistor is suitable rated and reasonably low tempco,
then monitoring the voltage tells you the current to a fair degree of
accuracy, so you can even work out how many coulombs are extracted
before a chosen end voltage is reached.

Besides, how many loads in your assorted appliances are constant
current?

We do discharge testing (as part of evaluating Li-Ion charging
systems) using precision logging equipment monitoring voltage while
discharging into resistive loads of known characteristics. The only
limit is the accuracy you require, and in your application a couple of
percent is probably the spec.

==========

I could monitor and log the voltage across a fixed resistance, draw a
curve, calculate the area... This would be a real pain in the rear for
the number of batteries I want to test. So I'd really like to find a
simple constant current device.

This Radio Shack digital multimeter does voltage logging on a PC:
http://www.radioshack.com/product.asp?catalog%5Fname=CTLG&category%5Fname=CTLG%5F011%5F008
%5F002%5F000&product%5Fid=22%2D812

The details on the software are vague. Does anyone have one of these?

Here's a cool device that would do the job, and then some. But I'd like to keep it just a bit simpler:

The video amp in most small B&W TV sets barely have a 2 MHz
bandwidth. look into a wideband op amp, or use a video hybrid amp from
a junk low resolution VGA monitor. National Semiconductor made some and
the data sheets should be available, online.

Please see previous thread.

I'm trying to match AA battery capacities so they can be used together in battery packs and I think created a low-tech way to do this. I'd like to hear more informed opinions.

This would apply to NiCads and NiMh but it should work with lithium-ions too.

Take all your batteries of the same type and charge them all in parallel to the same voltage. Then one at a time remove them from the float voltage and attach them to a fixed size resistor (say 6 ohms) for a fixed period of time (say 3 hours) then measure their voltage. Well matched batteries should have similar voltages.

Does this wash?

The only thing I wonder about is the full charge state voltage. Say I'm doing Ni-Cads which usually top-out around 1.65 volts (where they experience a voltage drop), and I set the float voltage for the bunch at 1.5 volts. Would the maximum voltage of each cell make a difference here?

Thanks for your help.

>Radio Shack.

One possibility is an LM317 voltage regulator, wired up with one
resistor between Vout and Vadj to create a current source (see the
data sheet).

Another possibility is a JFET, with source and gate shorted together.

Problem with both of these approaches is, they probably need several
volts of "headroom" before they begin acting as "stiff"
constant-current sources. If you're hoping to run an individual
1.2-volt cell down to, say, 1.0 volts to measure its useful capacity,
neither of these will work.

One thing you could do is simply discharge through a fixed resistor,
measure the voltage periodically, and use Ohm's Law to calculate the
current being discharged at each measurement time.

What's really important for matching in a battery pack is that the cells have very close to the same capacity. If one has lower capacity than the others, the others will reverse charge it after it discharges. This further reduces its capacity, making it go flat even sooner the next time. The absolute cell voltage at any point in the discharge process is unimportant.

Unfortunately, you can't discern the remaining capacity of a NiCd or NiMH cell by looking at the cell voltage. The only way to accomplish the matching is to discharge each cell until its energy is essentially completely gone (i.e., to 1.0 volt at moderate drains), and select cells on the basis of how long they take to get there. Ideally, the discharge rate would be about the same as in the device you intend to use the battery for. But in practice, the capacity of NiCd and NiMH cells isn't a very strong function of the load current, so you've got quite a bit of leeway.

Many years ago I made up a discharger for this purpose. It's basically an adjustable constant current load with an adjustable voltage comparator. When the voltage reaches the comparison voltage, it disconnects the load. An old analog electric clock is used to record the time -- the comparator also removes power from the clock. Initially set at 12:00, it directly reads the time it took for the cell to discharge to the specified voltage level. These days it would make a lot more sense to use an A/D converter computer board and/or a microcomputer chip of some sort.

> g0zen simon

Hi Simon,
My main frequency of interest is the 145MHz band. Frequency steps of 12.5KHz would be great, but 10K, 6.25K or 5K would all be of interest. I do have one project for the FM band, but that is low priority and I still need to do some work on the IF filter. Using TDA7000 as 21MHz IF stage where sensitivity is excellent, but input needs to be "clean".

I have been using the MB501 (SA701, MC12022, SP8704) but they are dual modulus. In my present application I am only interested in generating stable signals without modulation, so simple is good. Adjusting the reference freq is also an option. I know I could just buy a synth chip with internal prescaler, but again, choice is limited if I want parallel load and not a complete SMD project. One small SMD is Ok, but not the whole project.

As stated, the basic problem is getting a chip that is available, cheap and is likely to be available next year. The MB501 (SA701, MC12022, SP8704) is now classed as "obsolete" and one of my sources has also dried up. By the way, the TDA7000 is also obsolete and is soon to be joining the ZN414/5/6 and TCM3105 chips in the depths of obscurity.

I can agree with you, but only up to a point, but do you never think that "them there chips" can possibly be used as a tool? A component? A lot depends upon where you draw that line between what you call homebrew and black-box. Do you not think that an Operational Amplifier, like the UA741, is a component? or would you rather use a slack-handfull of transistors every time you need an Operational amplifier. I personally put the prescaler chip in the same category as the OpAmp.

> ... where's the fun in just hooking up power to a chip? That's
> not homebrewing, at least not in my book.

I get a great kick out of using CMOS and TTL chips. For example, one CD4007 can be used to build a complete superhet receiver. If I want a VHF synthesiser then I have absolutely no hesitation to using a couple of CD4000 chips and a prescaler. Logic, to me, is also homebrew. As I said before, it all depends upon where you draw the line.

> Try a simple flip-flop. Two transistors, that's all. There are probably a
few
> dozen schematics on the net and dozens more at the public library (you do
have
> public libraries in Sweden, don't you?).

I didn't have to search for a circuit, but using simple transistors I have a circuit that is stable, but only up to about 95MHz. Here in Sweden, the ONLY non-power RF transistor I can find in Sweden is the 2N2369 (NPN) and it is that transistor that has increased the operating freq. of my stage to 96MHz. I have also tried just a simple schmitt trigger circuit and again, about 100MHz is the top limit for conventional transistors.

Anyway, I am still having fun on the workbench and I will continue to do so. When I don't I will probably join all the others who are sick of radio and homebrew and get on the Internet. Prabably even subscribe to a hamradio newsgroup, such as "rec.radio.amateur.homebrew" and maybe even communicate with othere without the QRM.

Best regards - Harry (SM0VPO)

Fair enough - only you can decide what you enjoy. When you post to the group, we know where you're coming from, so we can interpret accordingly.

But only I can decide what I enjoy, only Harry what he enjoys, and so on for every individual. Amateur radio and electronics is about doing what each of us personally likes, not what we "should" or "must".

You are entitled to your own opinions about other people's preferences, Frank, but it's disrespectful to post them here as personal criticisms (and it doesn't encourage the rest of us to respect you).

When was the last time you saw a home-brew OP-amp? How many people that use the chips even know what an OP-amp is? Did you know that you can build an OP-amp with tubes? Did you know that you can build a prescaler with tubes? OK, so maybe that's not what you are looking for. But it sure defines "homebrew" better than a few chips thrown together on a proto-board....

After all, who's "brewing" this stuff -- you? or some semiconductor manufacturer?

Must be the latitude. For the sake of this discussion, I put whipped up a flip-flop that can do 240 MHz using 2N4401's. It took me about half an hour. You don't need to saturate those puppies, you just need a little gain.

Many years ago someone associated with NASA figured out that the
life expectancy of nicads (series or parallel use) could be increased
significantly by matching the internal impedances. The recharge/charge
life did not just double, but went up by a factor of ten (approx).
I think this was published in the some NASA Tech journal. It used to
be published about 10 times a year, it might still be.

Let me ask you a simple question: Suppose someone buys an SP-600, mounts some
chrome knobs, spray-paints his name on the front panel, then posts on the
newsgroup saying, "Hey, look what I built!" Would you call that "homebrew"?

Suggest you read the MAHA-C777PLUS User's Manual.

Chapter 2 (page 3) :
* Supports a wide voltage range from 1.2V to 14.4 V (1 to 12 cells) for NiMH
&NiCD and from 3.6 V to 14.4V (1 to 4 cells) for Lithium Ion battery packs.

I honestly don't share that compulsion to classify other people's
projects as either "homebrew" or not.

I guess you wind your own capacitors, and collect lamp black to make your own resistors? there are tradeoffs in any project. Sure you could build a 50 pound toy that uses 200 watts to do a simple project, or do the same job in a handheld device that runs for weeks off a couple AA cells.

Homebrewing is using what you can get to build what you want, as well as to meet the desired specifications. I started working with used parts in the '60s, but over the years I have moved on to more advanced projects. My biggest project to date, was building CH 58 TV in Destin, Florida with mostly defective and damaged 30 to forty year old broadcast equipment. It was a real challenge finding, or making replacement parts fore the RCA TTU-25B transmitter, and other old equipment. it was more of a restoration and homebrew project than it was meeting the deadline on the FCC construction permit. I ended up working as an engineering tech at L-3Com/Microdyne working on $80,000 telemetry receivers, and still design projects at home.

I am working on some kits to allow people to build some test equipment they can't afford new, and don't need the performance of brand new Agilent or Tektronix equipment. It is cheaper to use "Chips", rather than discrete parts in a lot of circuits, and they design works better, too. Homebrewing should be used to learn something, and if you want to remain at the lowest level, enjoy yourself, but don't ridicule others who want to learn newer methods.

Sorry, that isn't homebrew. You didn't build your own transistors, you used a prepackaged 2N4401. Where's the fun in that, it was mass produced in some factory in the far east. You don't say, but I also suspect you cheated by not fabricating your own capacitors with kitchen foil, nor resistors with bits of carbon rod.

The question of where you draw the line has to be answered by each homebrewer according to preference.

Here's a nice page with nice home-built components including a triode valve (tube): http://home.earthlink.net/~lenyr/vt-vac.htm

As I alluded to in my previous, I suspect you will find simple
constant current and 1v5 are relatively mutually exclusive unless you
want to go to low voltage op amps and roll your own.

I don't know what you are using to post your n/g messages, but I use a
PC. They DO have other capabilities besides internet connectivity.
It takes but a few lines of code - even in humble QBasic - to log the
voltages at set intervals, calculate current, and do time integration
to obtain joule or coulomb figures. Having a constant current device
as your load won't make this task any easier in reality.

>This Radio Shack digital multimeter does voltage logging on a PC:
>http://www.radioshack.com/product.asp?catalog%5Fname=CTLG&category%5Fname=CTLG%5F011%5F008%5F002%5F000&product%5Fid=22%2D812
>The details on the software are vague. Does anyone have one of these?

The average "affordable" RS-232 equipped multimeter seems to
invariably have a poor overall accuracy spec. This won't affect
repeatability or the validity of comparisons, but does obviously
impact on absolute numbers you obtain.

Harry,
have a look at the following page:
http://www.xs4all.nl/~barendh/Indexeng.htm
He seem to stock several old Plessey prescalers, and it should keep
you going for a while.

I guess eventually these chips WILL be nowhere to be found within a
few years time but that is evolution....

One non-obsolete chip-source would be Peregrine,
http://www.peregrine-semi.com/prd_pll.html
they have some neat parallell programmed IC's that runs to over 3 GHz.
They are an improved Qualcomm Q3036 which can be found as surplus
And there is several more interesting IC, not only PLL and prescalers
but complete PLL with internal EPROM which keeps the serial programmed
data even if one shut off the power. Great for that miniaturized
project!!

==========

Seems the RC car community matches batteries based on a number of
criteria like capacity, internal resistance, and average voltage. The
websites I found on this don't give specifics.

Buying a $200 pieces of test equipment to measure all this is slight
overkill. I think I came up with a way. What to you think of this?

Charge all the batteries in parallel to the same voltage, say 1.5
volts. Then partially discharge them all in series. At this point
quickly measure the voltage of each cell while still under load.
Matched cells would have the same voltage.

Do they have really cheap FM broadcast band only pocket radios over there,
that tune with one button (and have a second button to reset to the bottom of
the band)?

They're everywhere here, and I've seen them for as low as $1.99 Canadian.
Curious, I bought one at that price. No cermic filter, so it's using
an oddball scheme. My first thought was that it was a TDA7000; as I
mentioned a couple of weeks ago, the number on the IC was barely visible.
So I looked up the TDA7000 on the web (it was easier than digging out
the paper datasheet), and clearly it was not a match. But Signetics
had pointers to a couple of other similar ICs, ie converting down to
70KHz where active filters can be used, and that frequency locked loop
scheme. One of them was a match, if I'm remembering a 7088.

I don't know how the specs generally compare with the TDA7000, but
this IC has the logic in place for the two button tuning scheme.
Obviously these are being put into products (I always wondered if
the TDA7000 actually was put into commercial products), and hence there
is an available source. Maybe not as IC, but the cheap radio is there.
The IC is surface mount, but it's already soldered to a circuit board.
Change the required parts, and you've got the radio or IF strip.

I think there's a vast difference between that scenario, and building with
ICs. In your example, they are mere cosmetic work. But when building with
an IC, you will have to actually build something around it in order to
get something useful.

I am a bit surprised that you hold this opinion this late in the game.
Clearly, it was not an uncommon opinon thirty or so years ago, when
people would write to the magazines and complain about so many ICs
being used, and about how the internal diagram of the IC was not shown.
A lot of that could be discounted as a transitional reaction, that
since ICs were new people were reacting to the newness rather than
an absolute reaction to ICs being "cheating".

At least thirty years on, it's hard to imagine that there are people
who haven't adapted.

As others have pointed out, one can go down through a spiral to an
absolute level of "homebrew", but everything would be pretty bulky then.
Of course, early hams built their capacitors and all that, but it
was more necessity than some hard core belief. Once you could get
commercially available components, then they were used unless
a) someone was curious about making a capacitor or b) what was
exactly needed wasn't available.

There are some borderline parts. It hardly makes sense to buy
a commercially made coil if you can wind one yourself, but that's
not because everyone should be making everything, but because if
someone isn't winding, they may not realize it is a simple thing,
and winding will save money.

What ICs have done is allow for a level of complexity that wasn't
available before them. Sure, there were PLLs described in the ham
magazines using tubes, but they were as complicated as a simple superhet
receiver. I can remember seeing tube based synthesizers, using multiple
crystals mixed together, and they were more complicated than a full
blown transmitter.

If you want to build up a whole synthesizer from transistors, it's
going to be terribly bulky. I suspect few will go to that trouble,
and instead making something simple but which won't give the performance

of a synthesizer. There is so much that can be built nowadays that virtually nobody would consider building in the tube era.

So I dismiss your hardcore view on this.

On the other hand, there is validty in constantly thinking through whether something should be done with transistors or ICs. One shouldn't build with ICs for the sake of building with them; if two transistors out of a scrap VCR and some other components from it flash an LED perfectly well, then what's the point of using an expensive and hard to get IC that exists only to flash LEDs? If you don't lose anything in performance, and only a little space, then you might as well use readily available scrap transistors to build an IF strip, than spend money and time buying an IC via mail order. If two transistors will supply a suitable prescaler for Harry's project, then it likely is a good choice, because it's easier to find transistors than prescaler ICs.

But these are design decisions, not some rhetoric about how everything must be made from scratch. Any time something is designed, it's important not just to look at the way to do it, but at other alternatives, because people often do get blocked by looking down only one path.

For instance, as I write this it occured to me that it might be easier for Harry to mix the VCO signal down to a frequency where the average logic IC can work. You don't have to find a prescaler, and the design's frequency steps won't be limited by the division of that prescaler. There are various mixer schemes that will result in the needed frequency. There may be reasons for not doing it this way, but it may not even be explored because Harry hasn't given this alternative any thought.

I'm trying to get a hold of a tool that will undo grub screws
securing the front panel knobs on my venerable BC221, can anyone suggest
where I can get a hold of one, a modern equivalent and/or something that
can be modified to do the job ??
Although all BC221s were provided with the tool (stored in a
clip beside the spare valves) I've never seen one and can only guess
that it must be something like a very small Phillips screwdriver head
but with a parallel rather than tapered tip. It must also be less than
3/32" dia 'cos I've just tried to make one by hand out of 3/32" dia
steel rod and that was too big, don't think my eyesight is up to hand
filing the cruciform tip in any smaller dia rod, hence a request for
help !!
My BC221 is still furkling along after 63+ years (& only c/s -
There, I've said it !!) out of calibration) but I think I should at
least try & smarten up the case with a good clean and a bit of fresh
paint. Who knows, it's probably got more chance of making the century
than I have.
Thanks

Why charge them in parallel? Having them all charge the same in the real world should be part of the matching. In fact, if you start out with all batteries in the same state, and charge them in series, you can quickly pick out oddball by measuring the charging voltage across each cell.

It has been many years since I had a BC-221, but I seem to think that a Bristol wrench was needed to remove the knobs. No bets, however.

Over 30 years ago I homebrewed a PDP-8 work-alike computer. It was based on the PDP-8 instruction set. I've never seen PDP-8 electrical or detailed logic diagrams. I used ICs, but none more complex than a 4-bit adder. The 7400-series was then too expensive for me, so I used a cheaper compatible Signetic series in most cases. My choice to use ICs was based on a desire to finish the project within a reasonable time - which I did. There would have been too many parts going all-discrete. Of course discrete transistors were used as lamp drivers, to drive the core memory select lines, and in the voltage regulators.

> At least thirty years on, it's hard to imagine that there are people
> who haven't adapted.

Even using simple digital ICs, you have to know a little about the internals of the family to avoid pitfalls - and to interface to other families. Analog ICs require more understanding.

SNIP

> On the other hand, there is validity in constantly thinking through
whether

Or with a $2 microcomputer. IMO, evaluating the trade-off between hardware and software is just as important. Where should one draw the line?

My hobby RF experience has mostly been limited to VHF frequency converters.

OTOH I assembled the first FM-stereo broadcast station in the Washington DC area, WHFS 102.3 MHz. The "components" were rather large: an HH Scott stereo generator, an RCA "iron fireman" FM exciter, and a 1 kW power power amplifier that had seen service a number of other places. I built a frequency-multiplier / IPA between the exciter and the 4-400 finals, and the

power supplies including that for the finals. I built the stereo audio console for the station; my memory is a little hazy after 40 years, but I think the console used some audio ICs.

Hi Folks, I'm trying to locate the URL of the site containing the
following files
ft707.max
maxview.exe

Its the FT707 operating manual in compressed form readable only ,
afik, by the maxview program.

I've located a copy, but not the site I'm looking for, at
http://www.qsl.net/aa1do/
but its redirected to a timed out site.

I know I found it once, but I forgot to bookmark it.
Does anyone know where these file are to be found?.
Many thanks, Mike W

1348. FS: Old Radio Books

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-08-18 17:44:06 UTC
From: oldbooks78@aol.com
Message-ID: <20030818134406.21601.00000234@mb-m01.aol.com>
Source record: 33165

I currently have for sale the following old radio-related books. Postage is $2.50 for the first book and $1 for each additional item (Media Mail within the US, at cost elsewhere). The books are:

Worldwide Publications "White's Radio Log, Vol. I, Number I" Worldwide Publications, c1982. The 136 page softbound book is in good+ condition, clean with no page tears or pen marks. Not dated, but looks to be from the early 1980's. A directory of North American AM, FM, and TV stations including world-wide shortwave stations. Available for $3.

American Radio Relay League "The A.R.R.L. Antenna Book" American Radio Relay League, 1960. Nineth edition. The 320+ page softbound book is in good condition. The covers show some wear from previous use, there are a few bent page tips, and there is a previous owners address label inside the front cover. A good solid reading copy of this informative text on radio antenna technology. Available for $4.

Federal Telephone and Radio Corporation "Reference Data for Radio Engineers, 2nd edition" Federal Telephone and Radio Corporation, 1946. Second edition. The 322+ page hardbound book is in about very good condition, clean with no page tears or pen marks except for a previous owners name stamp inside the covers. Green cloth covers. A nice early radio reference text. Available for $7.

Federal Telephone and Radio Corporation "Reference Data for Radio Engineers, 1st edition" Federal Telephone and Radio Corporation, 1943. First edition, second printing. The 200 page hardbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. The pages are a bit wavey along the bottom edge, possibly from minor moisture exposure. Otherwise very nice. Green cloth covers over flexible boards. A nice early radio reference text. Available for $10.

Everitt, William Littell "Communication Engineering" McGraw-Hill, 1937. The 727 page hardbound book is in about very good condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover, and a few passages underlined in pencil. A nice early text on the science of the radio. Available for $9.

Jordan, Edward C.; Paul H. Neilson; William Carl Osterbrock; Fred H. Pumphrey; Lynne C. Smeby "Fundamentals of Radio" Prentice-Hall, 1945. Twelth printing. The 400 page hardbound book is in very good condition, clean with no page tears or pen marks. A nice early text on radio design and principles of operation, including a few fold-out schematics. Available for $9.

Terman, Frederick Emmons "Fundamentals of Radio" McGraw-Hill, 1938. First edition, seventh printing. The 458 page hardbound book is in about very good condition, clean with no page tears or pen marks except for a previous owners

name and address inside the front cover which has been marked out. A nice early radio reference text. Available for $9.

Institute of Radio Engineers "1933 Report of the Standards Committee of The Institute of Radio Engineers" Institute of Radio Engineers, 1933. The 225 page softbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name on the front cover. Some wear to the spine paper, but not too bad. Page tips in rear lower corner bent outwards somewhat. A neat look at standards development for the radio in the early 1930's. Available for $8.

Measurements Development Laboratory of the Sperry Gyroscope Company "Microwave Transmission Design Data" Sperry Gyroscope Company, 1944. Publication No. 23-80. The 215 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Originally issued during WWII as a "confidential" document. Chapter topics include General formulae for concentric lines; Attenuation in concentric lines; Reflections and impedance matching; General formulae for wave guides; Attenuation in wave guides; Reflections and impedance matching in wave guides; Wave guide tees and bends; Wave guides filled with dielectric material; Dielectric material: Cavity resonators; and Measurement techniques. A neat early book on ultra-high frequency radio waves. Available for $8.

US War Department "Technical Manual - Radio Fundamentals, TM 11-455" U.S. GPO, 1941. The 140 page softbound book is in fine condition, fresh and clean inside and out except for a previous owners name on the front cover. A nice WWII vintage radio manual. Available for $8.

Morecroft, John H. "Elements of Radio Communication" John Wiley & Sons, 1929. The 269 page hardbound book is in good+ condition. There is a previous owners name inside the front and rear covers, and light pencil marks/notes on many of the pages. Dust jacket has extensive tape reinforcement along the edges. A nice early text on the radio. Available for $10.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks.

Dave

| should because of mismatches in cell capacity.

Well, if you don't mind spending some money --

http://www2.towerhobbies.com/cgi-bin/wti0001p?&I=LXCJG7&P=7

This is a great charger. Not only does it do a great job with my R/C
plane batteries, but it does my ham batteries too. It can charge or
discharge 1-24 cells, and can do NiCd, NiMH, Li-Ion, Li-Poly or lead
acid bateries.

For one battery, you just charge the battery, then set it to discharge
at perhaps 1/4 C, and tell it to cut off at 0.9 volts. Once done,
you'll know exactly what capacity it has.

As another poster mentioned, the R/C communities know all about
batteries. Read their stuff on it, you'll learn a lot. :)

Oh, if you do use a charger like this to charge a battery, be sure to
make sure you've got a direct path to the battery itself -- trying to
push 1 A through a charge circuit that lights up a LED and such is a
great way to let out the magic smoke -- even through the battery can
handle it no problem.

If this is too much for you, there are other alternatives, but few are
so flexible for this `little' money.

Hans Summers <Hans.Summers@tudor.com> wrote:

: Naturally the type of display this tube is now being subjected to is very
: different to a TV picture. There seem to be some problems with the video
: drive circuits, see pictures at the bottom of the above web page. The
: graticule fades out in the top eighth of the screen.

That looks like a video DC-restoration problem. Try mixing your TTL video signal with the composite sync signal in order to obtain a more TV-like video signal. Note that the video amplifier is AC-coupled to the picture tube and DC-restoration is done in that case by the CRT itself, the cathode and grid electrodes work like a diode that clamps the video signal to the sync level (no sync pulses = no proper DC-restoration, brightness will fluctuate with video contents). The time constant of the RC coupling to the CRT should be high enough (in your case it is).

: Also see the "noise floor" photo which shows significant horizontal "bulge".

That could be due to poor HV regulation (check by reducing the brightness, if the image looks OK when you have just a faint image, then the problem is the HV). That's is a problem of using a normal TV for digital signals, and there is not much that can be done, other than redesigning the whole horizontal sweep circuitry (needing perhaps a different flyback). Check in any case the DC supply to the horiz output for fluctuations. Computer monitors are much better in that respect.

: Also there is a resolution problem - one spectrum analyser sweep consists of
: 640 measurements, and I have a complicated interpolation circuit which
: "joins the dots" i.e. draws lines between the individual measurements, and
: also reduces the horizontal resolution to 320 pixels which I hoped would be
: displayable on the monitor. Problem is I can only get 160 horizontal pixels
: to display reliably - at 320 pixels a vertical line is very faint or
: invisible (depending on how much white there was in the preceeding
: microsecond or so's worth of scan line.

That's a bandwidth problem in the video amplifier. You may begin by removing the audio IF trap (the L-C connected to the emitter of the video amplifier), but I don't think that would help that much. Try using a higher frequency transistor for the video amplifier, you should choose one with low b-c capacitance, a cascode amplifier will do a better job since it does not suffer from Miller effect problems (you might need a bit higher voltage supply for the amplifier, though). A small inductance in series with the 8K2 resistor in the collector ("peaking coil") should improve high-frequency response by compensating for the CRT input capacitance.

Hope that helps a bit.

Regards,
Hector.

It's not difficult. I use an supply to power an op amp which senses the current across a small resistor and drives a power FET. It does fine down to less than one volt. In fact, it was actually designed to use as a constant current source for charging a NiCd battery from a solar panel, and it does double duty as a constant current load for testing battery and cell capacity.

Hi,

You are correct Bob, according to the SCR-221 technical manual (TM-11-300) there should be two Bristol wrenches (#6 & #8) in the spares kit. I have just tried the one I have on an old wreck of a BC221-T and it fits but don't know whether it is a #6 or a #8. It is just under a 1/10" across the flutes.

I believe that during WWII there was a specially employed lady, complete with tattoos presumably, whose task it was to tighten the set-screws on all military equipment. She did such a good job that nobody except a certain candidate for the governorship of California has since been able to move them.

Cheers - Joe

Bruce,

Here is a crude way to do unattended tests. There are any number of cheap battery powered clocks that run off 1 or 2 AA cells; you would use external power instead. Put one of these in parallel with your load, and see how long the clock runs. You could add an opamp to set the trip point to a particular voltage. Use an opamp whose common mode range includes the negative rail.

That's a great idea.

It wouldn't really be important to trip at a particular voltage if you're interested in finding out the capacity, provided that the clock will run at one volt (which any device designed to run from an alkaline cell certainly should)(*). There's very little energy left when a NiCd or NiMH cell reaches one volt, and the cell voltage will drop from there to the point where the clock shuts off in a very short time compared to the total discharge time.

Roy Lewallen, W7EL

(*)Unlike NiCd and NiMH cells, an alkaline cell still has a subtantial amount of energy left when the cell voltage is one volt, assuming a low or moderate load. Well designed devices running from alkaline cells should operate down to about 0.9 volt per cell at low or moderate drain, or about 0.8 volt at heavy drain, in order to extract nearly all the cell's energy. Ideally, a NiCd or NiMH powered device should disconnect from the battery at one volt/cell to prevent reverse charging of a weak cell. Even that isn't sure-fire if there are more than about 5 cells in series, and if one is considerbly weaker than the others.

Popular Photography tested AA alk batteries by repeatedly firing off the flash until the recharge time became 10 seconds, or something like that.

>who haven't adapted.

Adapted? Yes. I have built countless devices around IC's of just about every shape and size. But I didn't design or build the -circuits- (i.e, the amps, the oscillators, the comparators, the negative impedance converters -- the network of active and passive components that make the device do what it does), I just followed the instructions provided with the chip and connected the dots.

>As others have pointed out, one can go down through a spiral to an

>a) someone was curious about making a capacitor or b) what was
>exactly needed wasn't available.

The "level" of construction is the issue. It's one thing to homebrew the components, but another to homebrew the circuits. I understand what you and everyone else is saying, that "homebrew" can include the use of pre-packaged circuits as components, that it's just a different "level" of construction. Some might even think that building something from a kit is homebrew. I don't. Somebody else "brewed" the circuit -- the kit-builder simply assembles the

components (connects the dots).

Superhets aren't that complicated, and neither is crystal mixing. Regardless,
crystal mixing can get expensive.

>If you want to build up a whole synthesizer from transistors, it's
>going to be terribly bulky. I suspect few will go to that trouble,
>and instead making something simple but which won't give the performance
>of a synthesizer.

Not true. Try linearizing a VCO and using a stepped voltage divider, then
beating the output against an OCXO for drift correction. It's an old method, but
it still works great. And it's a lot less complicated and expensive than using
multi-bit comparators, parallel ripple counters, a parallel-to-serial converter
(because there are very few parallel PLL chips anymore), BCD rotory switches or
a decimal-to-binary converter, phase detectors, prescalers, etc. And notice that
you still need that pesky reference oscillator!

> There is so much that can be built nowadays that virtually
>nobody would consider building in the tube era.

I agree. But I didn't say that every homebrew project must be built with tubes.

>So I dismiss your hardcore view on this.
>

>must be made from scratch. Any time something is designed, it's important
>not just to look at the way to do it, but at other alternatives, because
>people often do get blocked by looking down only one path.

And that, too, is a very good point. Notice that it works both ways -- I see a lot of homebrewers getting stuck in an 'IC rut'.

>For instance, as I write this it occured to me that it might be
>easier for Harry to mix the VCO signal down to a frequency where

>that prescaler. There are various mixer schemes that will result
>in the needed frequency. There may be reasons for not doing it this
>way, but it may not even be explored because Harry hasn't given this
>alternative any thought.

And the synth will be more accurate than using a prescaler, even a dual-modulus prescaler. But I made the mistake of assuming that he knew the difference between the two methods and had chosen the prescaler over down-conversion for reasons unmentioned.

I have seen the wrenches on e-bay from time to time.

To remove the screws after ordering a bowflex machine and working out with it for 6 months, heat them and the "glue" will release and you will be able to turn them.

OK Frank, I'm interested to see a picture and a schematic of your circuit. Do you have web pages like Harry's?

I can't help but think that you have been more than a little rough on Harry, someone who obviously does "homebrew" his stuff. I wish I had the time patience and ability to construct more stuff that actually worked myself ;-). Perhaps I'm lazy but I'll choose a suitable IC over a descrete solution 9 times out of ten. I'm not sure why you have a downer on using IC's.

I sympathise with Harry's difficulty in getting hold of parts in Sweden as it is getting difficult to find (hobbiest) RF parts in the UK.

The hobby of radio and electronics construction is dying in the UK, so we should be happy if some people build only kits, otherwise the kit suppliers will go out of business too.

regards...

You might check inside the instrument. A Bristol wrench was often
included in military gear under a clip someplace.

I don't have a Bristol wrench for comparison any more, but I recall
their cross sectional shape as resembling modern Torx drivers. It would
probably take an unusually long one, and if it didn't fit well there'd
be a danger of chewing the screw so it'd never come out. Might be worth
investigating, though.

Say for a NiCad or NiMH battery, how is battery capacity calculated?
Say I put a resistor across the battery and measured the voltage
periodically. Is it the area of the curve above 1.1 volts, 0.9 volts,
or what?

Thanks for your help.

1372. Re: Prescaler? Suggestions anyone?

The lower level is trying to force someone to do it your way.

By working with ICs, you learn how to work with complex circuits.
Your two transistor FF is a text book circuit anyone can copy. Build a
low phase noise PLL synthesized signal source for a commercial radio
that operates over three band segments and has a level output, along
with low spurs and low power consumption, then tell me how to do it with
discrete components.

After almost 40 years of both homebrewing and commercial design I
have learned the simple tricks when I was a kid, and I want to keep
learning. On the other hand if you can't learn you can just keep on
building the same things, over and over. The last design I was involved
in was a dual receiver microwave (P, UL, LL, bands) telemetry system
that was DSP based, with FIR filters in both of the the IF and video
filters. The radio had millions of transistors in the hundreds of
I.C.s, and only a couple discrete transistors used in simple gain
stages. The schematics fill 35 size "E" pages, and the test and
alignment data is almost 1000 pages.

Like I have said before, "Do what you want, but don't tell someone
else who to design and build their projects."

You can measure it either in watt-hours or in ampere-hours. The first is the true energy delivered, and would be the area under a voltage-vs-time graph at constant discharge current. If current isn't constant, you would have to measure the voltage and current at each time interval to be rigorous, plot the product of V and I vs time, and integrate that function.

However, capacity of NiCd and NiMH cells is just about always specified in ampere-hours, or milliampere-hours, since the discharge voltage is fairly constant anyway. That can be measured by simply discharging the battery at constant current and multiplying by the discharge time. If the current isn't constant during discharge and you wanted to be accurate, you'd have to measure the current at various time intervals, plot that against time, and integrate the result. Of course, a simple rectangular or triangular integration would be simple to do even with a spreadsheet, or a very simple program in the language of your choice, and would be entirely adequate for the job.

But because a NiCd or NiMH cell voltage stays pretty constant between 1.2 and 1.25 volts during the majority of the discharge period, you could also discharge it with a resistor, then estimate the average current by assuming a voltage midway between those values, and simply multiply by the discharge time. That would be close enough for most purposes.

1.0 volts is the usually specified cutoff for NiCd and NiMH cells. When the cell voltage reaches that value, there's very little energy left, so the voltage falls very rapidly beyond that. There's actually very little energy left at 1.1 volts with a normal cell, but one suffering from voltage depression (the so-called "memory" effect that's cured by discharge to 1.0 volt) can deliver quite a bit of energy at 1.1 volt.

I can think of a lower level -- saying that I'm trying to "force" anybody to do
anything simply by expressing my opinions.

I actually built a vacuum tube op-amp in high school. We had a student
teacher who urged me to do this, but I had no idea what I was up to. I
just thought I had this really high gain amp that I couldn't get to do
anything.

It was years before I actually got taught about op-amps and I'm
ashamed to admit that it took another couple of decades to recall the
high school incident and remember that the student teacher was trying
to tell me that I needed to add other components around the op-amp to
make it useful. I'm afraid I just didn't get it at the time. I
couldn't imagine why anyone would want to cut down the gain of this
really "cool" amplifier....

Because when there is the alternative, you can learn a whole lot more by building circuits from discrete components; and many times those circuits are much better suited to an application than a chip, but people don't realize it because wiring chips is easier than learning how a circuit actually works. For example, I dug up a schematic I found in a book many years ago. It is for a "unanimous vote detector" and uses two 7400's, two 7404's, eight switches, an LED and a resistor.

Two thoughts keep running through my head that may or may not be true: The first thought is that semiconductor manufacturers are constantly trying to develop new technology that works just as well as old technology but is more complex, more expensive, and therefore more profitable; the second is that too many people assume that new technology is necessarily better than old technology.

>I sympathise with Harry's difficulty in getting hold of parts in Sweden as it
>is getting difficult to find (hobbiest) RF parts in the UK.

It's not like we have prescalers growing on trees around here, either. I started in electronics with whatever I could find, and since I didn't know about all the resources I had available, I didn't find much. For instance, I didn't realize that just about every FM broadcast receiver (even the cheap ones that people throw away as junk) has at least a couple VHF transistors in them, one for the

LO and one for the front-end. Junk TV's have both VHF and UHF semi's. Old computer boards frequently have high-speed switching transistors that make pretty good high-gain amps all the way up through VHF (and would be ideal for a high-speed flip-flop). Junk CB radios have lots of goodies, including power transistors that can work in the low VHF. Even tubes (valves) can be reasonable substitutes for some modern-yet-unavailable electronics. For example, a pair of triodes in cascode makes a mighty quiet front-end for a receiver, comparable or better in performance than many modern FET's. And several common miniature tubes can be used as high-frequency amplifiers, even as power amps capable of a few watts, well into high VHF. Etc, etc, etc.

When you learn about all the different components, their capabilities and applications, and the circuits in which they are used, it's hard NOT to find what you need REGARDLESS of what corner of the world you reside. But you don't really know what they can do until you use them. Sure, the same is true for chips. But I know I would get much more satisfaction by building a high-speed flip-flop using vacuum tubes than I would wiring up a 7473 on my proto-board. Come to think of it, that sounds like an interesting project for this winter.

I wonder what vacuum-tube technology would be like today if tube manufacturers had continued to develop them after the invention of the transistor....hmmm....

>The hobby of radio and electronics construction is dying in the UK,

It's not exactly flourishing in the states. One exception is the growing interest in radio piracy. The lack of broadcast transmitters available to the general (and usually unlicensed) public has been a boom for any company that builds kits for broadcast transmitters and RF amps.

:-) Yep, indeed. In fact, my older daughter bought a new faceplate
for my younger daughter's cell phone as a present, only it turned out
to be a whole new case (clear plastic). Yours Truly got to replace
the case, which was held in with #6 Torx. I was happy to find that
one of the Bristol spline wrenches from an old GC set fit just fine,
as my Torx drivers go down only to #8 here at home. So you MAY find
that a #6 or #8 or #10 Torx will work in your BC221. Mebbe I'll go
try it on my LM (Navy equivalent of the BC221) and report back.

Cheers,
Tom

Usually they pick a voltage that lets you get some large percentage of
the total available energy. I think 1.0V is OK for a NiCd, though you
could be more conservative and use 1.1V. There probably isn't much
energy left by the time you reach a volt, at least at modest current.
It also makes a difference what rate you discharge. So for a 500mA-H
cell, if you discharge at 50mA, that's a "ten hour rate" and would be
a common way to rate the cell. If your application draws heavier
current, you'd be advised to test at that current, and you will find
the mA-H value to be lower than at the lower rate.

I'd think you could find lots of info on the web about this, since
it's a common topic. I've seen quite a few articles in various trade
journals about it.

Cheers,
Tom

Hi Michael,

Yes, we do have those wireless sets. The cheapest I have found is 69 crowns (US$9) which is still quite expensive. But then again, the TDA70xx ICs are also quite expensive, or obsolete. I am seeking a source of the chip outside Europe for my kits.

Hello Michael. Down-conversion has been considered, but quickly dismissed. The sysnthesiser I need is a tool to be used for a wide variety of projects: projects that include modulation.

Down conversion of frequency preserves any applied modulation. The prescaler and subsequent dividers filter out modulation so that a true phase lock may be achieved. This is especially true with WBFM where the total divide rate must be greater than 10000 to achieve a phase lock. NBFM, with a minimum modulating freq of, say, 250Hz, still needs a divider to divide by more than 60.

Down conversion could make a simple synth if modulation were never to be used. I intend the project area to be both TX + RX, and to become a "building block" for a variety of circuits.

Anyway, I have received a lot of response. My original question was "is there a good cheap source of prescalers" (but in a long-winded way) and this I have received. Many thanks to you and all who have given me positive suggestions. Unfortunately I will not be melting down horses hooves to make the glue to bond the home-beaten copper to a board to make the PCB. The only thin board available would be ready-made plywood, and that would not be "homebrew" ;-)

BR Harry

I'm not an expert on SMPS design, and espcecially not on the little
tricks that make the difference between just working and working well.
Obviously the extra complication of the split winding is there for a
reason, and my guess would be that it's to improve the high-frequency
performance by minimizing leakage inductance. Anyone else know for sure?

You may also be running into trouble by ordering un-wound cores, since
you don't know the specifications of the existing ones (permeability,
Bmax etc).

>which makes winding the secondary a pain as its in the middle, and i am sure

>not needed...

The basic turns ratios are OK... the details, I'm not so sure about.

Can anyone recommend a book on SMPS design that leads you all the way
from basic theory to real-life designs - including all those little
practical details that need to be right?

WHAT? Even -with- modulation all you need is a low-pass filter on the output of
the phase detector, which is what you have to do anyway. The phase lock is
"true" whether you have modulation or not, it just takes a couple extra
milliseconds to lock. If the VCO drifts faster than that then you have some
other problems that have a higher priority than a prescaler.

BTW, if you don't have any transistors in Sweden that will work at 100 MHz, what
are you using for your VCO?

From what you say about the availability of materials in Sweden, do you need any help finding some quality plywood (not obsolete, of course), and maybe an inexpensive source? You might try posting in alt.plywood.pirate.....

You are deeply mistaken if you believe that "simply expressing my opinions" exerts no force on other people.

Earlier, you mentioned someone who was proud of having repainted the front panel of an old communications receiver. That person may not yet have the knowledge or the confidence to tinker much inside the case... but with help and encouragement, they will.

Now what kind of encouragement is it, if someone more experienced comes along and dismisses their beginning efforts as "not homebrew"? Certainly you will have a private opinion - but will opening your mouth make them more likely to stay with electronics and learn something... or less?

More than 40 years ago, I actually *was* that beginner who started "electronics" with a paintbrush. I've only just realised how lucky I was to have escaped a put-down, right when it could have done the most damage.

======
Discharge the fully charged battery at a constant current until the voltage
has dropped to 1.0 volt per cell
A simple constant current drain can be made with a LM317 voltage regulator
used as a constant current regulator up to 1 ampere ,by tying the reference
leg 'downstream' of a resistor connected to the output leg.
Since the LM317 needs some 'head voltage' ,this system works well as from 3
cells in series , hence 3.6 V.
For 12 V and higher battery packs an additional resistor is advisable to
dissipate part of the discharged energy , alternatively you can use a LM
7805 voltage regulator in the same way, without an additional resistor.

Thanks Roy.

I found a good way to measure the capacity of a single cell. This Radio
Shack multimeter:
http://www.radioshack.com/product.asp?catalog%5Fname=CTLG&category%5Fname=CTLG%5F011%5F008
%5F002%5F000&product%5Fid=22%2D812

It logs voltage (or current) and its software can output the log to a text file. Now all I have to to is write a little computer program to calculate the capacity.

I think Western Electric made this same type tube for 4 and 6 GHz
as well as 10 GHz. AT&T had equipment that operated in the 10.700
to 12.500 GHz range (Those freq. are close if not exact).

That CRT comment was about as wrong as can be.
The "CRT" was a magnifier glass to read the film strip dial.

Should have looked at the unit before commenting.

Geez, brilliant response Frank. A guy needs help finding a prescaler
and you tell him he just needs a bucket full of transistors. Why not
vacuum tubes or mechanical counters?

Here's some help for your next project Frank. Just get a bunch of
wire and solder and electronic parts and stuff and hook it all
together. Like freshman lab, remember? But from your communications
style, I suspect you're still in high school.

Nick

I have a similar meter that seems pretty accurate, and because the
voltage is around half of one of the full-scale ranges, you don't
sacrifice much because of poor resolution (as you would at, say,
2.1V).

An easier way (for those of us who don't want to deal with programming
access to the info) than writing a program is just to import the text
file to a spreadsheet. You then have a column of voltages at uniform
time intervals. If you know the discharge resistance (load
resistance), then I=V/R and you can make a column of that value. The
power at each interval is just V*I -- or just go to that directly as
V^2/R. Then the total energy is the integral of the power over
time...in watt-seconds, just the sum of the power column, if your time
interval is one second. Divide by 3600 seconds/hour to get
watt-hours. Sum the amps column to get amp-seconds and divide by 3600
to get amp-hours.

I've done exactly this sort of thing with my RS-232-interface
voltmeter. Works fine.

Cheers,
Tom

Many, MANY years ago I wanted to remove the knobs from several pieces of
equipment (BC-610 tuning units vaguely comes to mind), and I recall that
I stripped an average of one properly-sized Allen wrench per knob removed.
Fortunately, the town where I was living at the time (Fort Collins, CO)
had a "war surplus" store, and -- even more fortunate for me -- they had
bins AND BINS of Allen wrenches of the proper size for a dime apiece!
Needless to say, I bought a lot of them!

You need Bristol wrenches or Bristol keys or whatever Bristol calls them. They come in 4 or 6 point form. The 6 point ones look very much like Torx head screws. You need the 4 point type. I got mine from McMaster Carr:

mcmaster.com

I don't know if Bristol wrenches are easily available in the UK. McMaster's website seems to be down right now, but I have to figure they do international orders.

Let me clue you in here: I can't force you to read my posts. I can't prevent you
from tossing me in your killfile. And while I -can- write a post that offers a
different perspective on an issue, I -can't- make up your mind for you. And in
case you didn't notice, a newsgroup is a temporal medium -- i.e, if anyone feels
that I am forcing them to do anything it's because they have a very weak mind.

>Earlier, you mentioned someone who was proud of having repainted the

I'm glad to hear that your fragile ego has not been disturbed by people like me
who are not afraid to tell it like it is. I may take an in-your-face approach,
but that happens to be my personality -- I don't walk on eggshells, I don't play
pop-psychology, and I don't coddle someone for doing mediocre work when I know
they can do better. If painting was all you could accomplish 40 years ago,
consider yourself proud to have learned something more about electronics since
then. But now that you have more knowledge and experience, do you still think
that homebrew electronics includes doing nothing more than painting the front
panel of a radio built by someone else? If so, then we have widely different
perspectives on the subject.

I think that Harry is selling himself and his readers short by not even considering the use of discrete transistors (claiming that he can't find any that are fast enough but still hasn't said what he plans to use for a VCO). I know that he is certainly capable of making a high-speed flip-flop that will work for his application, and probably better than any prescaler chip he can find. Whatever he chooses, it's his choice to make. But it's also MY choice to speak up if I think that he is ignoring a better alternative. And also to point out that for a very public ham such as him to ask for help in a pirate newsgroup probably isn't the best way to further the legitimate radio hobbies.

Now, how am I "forcing" anyone to do anything?

That's all a chip is anyway. It's just a really small bucket.

> Why not
>vacuum tubes or mechanical counters?

The vacuum tube flip-flop is a neat idea, and I have that on the list for this winter. I don't think a mechanical counter will work at 100 MHz.

But maybe -you- can help Harry out in another way: He says that he can't find any transistors that will work above 100 MHz, yet he is building a synth to work at least that high. So what should he use for the VCO? A vacuum tube? Or a really, really small tuning fork?

Gee, I'm hurt. Maybe someday in the future, when you sift through the archives and read this thread again, you might do so with an open technical mind. Oh, and maybe a behavioral therapist holding your hand and to provide counseling for the trauma of learning that not everyone behaves according to the edicts of some middle-aged newspaper columnist.

How about providing explicit instructions to build a homebrew project (basically a pirate FM broadcast transmitter) that Harry openly admits is "illegal to use or build in many countries"? No, I don't suppose that "exerts no force on other people". Does it influence people? Even though he puts up a disclaimer stating that he will "accept no responsibility what-so-ever for any ilegal use", does it encourage people to break the law? How about that freedom-of-speech clause where he states that "This circuit is provided solely as an educational project". Is he allowed freedom of speech, but not me?

Also, a metric or Torx wrench might get enough bite in the damaged socket head screw. If you do go for the drill, try to find a bit with a left hand twist. If it locks in the set screw, it might well spin it out.

==========

I wrote the program and will make it available to anyone that wants it.
I runs on Windows and the .NET Framework. Works fine. The only problem
I have is remembering to disconnect the battery from the resistor after
it hits one volt, Doh! Some of them were pulled down to 0.4 volts
(under load) but they recover to about a volt at rest.

Yet one question still lingers in my mind. Is a discharge voltage to,
say, 1.1 volts under load or at rest?

Sure it does! Imagine that you want to listen to 146.52MHz and
there's a weak signal there. Imagine that you have a couple local
repeaters on 146.62 and 146.72MHz. Where are the third-order products
from the repeaters? One lands right on your weak signal. This sort
of thing is specifically a problem at repeater sites where there may
be many transmitters sharing the same mountain top or tower.

Cheers,
Tom

Source record: 33135

The end discharge voltage (generally 1.0 volt per cell for NiCd and NiMH cells) is measured under load. After disconnecting the load, the voltage will typically rise substantially, but its value isn't of any significance.

It's usually not recommended to discharge below 1.0 volt, but it doesn't seem to cause any harm, at least if it's not done really often. I think a cell is more likely to grow dendrites and short if it's left in an extreme discharged state for an extended period, so it's probably a good idea to put at least some charge back in before too awfully long if you've discharged it particularly deeply. What is harmful is reverse charging of the cell. But that happens only when you have an external source of current, like other cells in a series connected battery.

Absolutely agree. The 2 meter FM transceivers of the '70s were prime examples. I used to have a Drake TR-22 that received false signals when certain local repeaters were transmitting at the same time. Later transceivers had much better IP3.

I had no trouble getting a SMPS transformer apart when I put it in a
sealed can with some MEK solvent and left it for 24 hours. I put some
scewed up wire mesh in the bottom of a small can to elevate the core,
so that it was only exposed to the vapour, and not immersed in the
MEK.

The E-cores separated with minimal force and with no damage after this
treatment, and the MEK did not affect the bobbin.

Make sure the can is properly sealed. I left the can outside to
minimise any exposure to the MEK fumes.

The "capture effect" of FM means that in general you either don't have a problem, because the wanted signal is the stronger one... or else you have a big problem.

One of the problems with FM is that because everything's channelized, IMD products are sure to fall on another channel.

With a shared site, you can also get third-order IMD problems that only arise when a particular combination of three transmitters are activated at the same time. It can even happen if one or even two of the transmitters aren't actually on that site. Such intermittent problems can be a pig to track down - especially when you don't have authority to do it the easy way, which is by turning off other people's transmitters!

If this doesn't happen often, and you're not up there at the site to monitor the audio on the digital link, you may not even be aware of the increased retry count. On the other hand, that probably also means you can live with it.

We are wandering way off-topic here so I'm a bit reluctant to post this on r.r.a.h

Ah! what the hell!, it's only a few KB of text....

The following is an actual question given on a University of Washington chemistry mid-term. The answer by one student was so "profound" that the professor shared it with colleagues, via the Internet, which is, of course, why we now have the pleasure of enjoying it as well.

Bonus Question: Is Hell exothermic (gives off heat) or endothermic (absorbs heat)?

Most of the students wrote proofs of their beliefs using Boyle's Law (gas cool when it expands and heats when it is compressed) or some variant. One student, however, wrote the following:

"First, we need to know how the mass of Hell is changing in time. So we need to know the rate at which souls are moving into Hell and the rate at which they are leaving. I think that we can safely assume that once a soul gets to Hell, it will not leave. Therefore, no souls are leaving.

As for how many souls are entering Hell, let's look at the different religions that exist in the world today. Most of these religions state that if you are not a member of their religion, you will go to Hell. Since there is more than one of these religions and since people do not belong to more than one religion, we can project that all souls go to Hell.

With birth and death rates as they are, we can expect the number of souls in Hell to increase exponentially. Now, we look at the rate of change of the volume in Hell because Boyle's Law states that in order for the temperature and pressure in Hell to stay the same, the volume of Hell has to expand proportionately as souls are added.

This gives two possibilities:

1) If Hell is expanding at a slower rate than the rate at which souls enter Hell, then the temperature and pressure in Hell will increase until all Hell breaks loose.

2) If Hell is expanding at a rate faster than the increase of souls in Hell, then the temperature and pressure will drop until Hell freezes over.

So which is it? If we accept the postulate given to me by Teresa during my Freshman year that, "...it will be a cold day in Hell before I sleep with you," and take into account the fact that I still have not succeeded in having an affair with her, then #2 above cannot be true, and thus I am sure that Hell is exothermic and will not freeze over."

THIS STUDENT RECEIVED THE ONLY "A".

As anyone who lives in Scandanavia and grew up with Norse myths should know, hell is frozen. Heaven is the warm place you go after freezing your behind off your whole life. Here in Texas 100F in the summer is a small price to pay for 70F in December. My cousins in Wisconsin still put up with -35F in the winter, I consider Texas heaven and Wisconsin hell.

No ice build up on antenna towers, and your mobile station doesn't rust out after 10 years from the salt on the roads (just to put a little amatuer content in the message).
thanks, John.

One of the best reference books for just about everything
dealing in electronics, is an older copy of the ARRL, Amateur
Radio Handbook. The older ones are the best as far as I am concerned.
Try used book stores, amateur radio flea markets etc. Hardly a day
goes
by that I am not looking up something in one of the 5 that I have.

Also look on ebay. I've bought several there (all the way back
to a 1937 edition) for very little money.

MEK - Methyl Ethyl Ketone - it's used as a solvent in some
industrial paints. One can buy it from a paint shop here in ZL, along
with other solvents like xylol.

Methyl Ethyl Ketone, a moderately nasty solvent. If I recall properly
it is (or was) a common ingredient in fast-acting paint strippers.

ok then MikeN i guess you were moding a psu, was it a computer psu and if so what was your final voltage, asking as i would like to know how many secondary turns you wound for your required voltage, asumming running at about 33khz 230v ac before rectifier etc...
oh MEK?? i have cellulose thinners to hand..but no transformer to split untill i get my hands on some more psu's, (when i venture back into the attic!)
sorry if these questions sound simple, but i am really keen in not having to wind douzens of transformers before i get it correct..
